EXECUTIVE SUMMARY

New Gold Rainy River Mine completed Phase 1 Eastern-Whip-poor-will monitoring of the mine site and periphery in 2022 as per Condition 6.1 a) and 6.2 (a)-(g), following the schedule outlined in Appendix G of *Endangered Species Act Overall Benefit* permit FF-C-001-14. Although not scheduled in 2022, Phase 2 Eastern Whip-poor-will monitoring within the Overall Benefit Areas was also completed. Sound monitoring of two receptor sites north and south of the mine was performed to determine if the sound threshold of 50 dBA was reached per condition 4.2(b).

Bald Eagle and Barn Swallow nest monitoring was conducted following requirements of provincial Environmental Assessment notice of approval Condition 5 detailed in New Gold's Follow-up Monitoring Plan.

Eastern Whip-poor-will surveys were completed following MECP guidelines at 50 stations within the Phase 1 mine site and periphery areas. Forty-eight (48) survey stations were completed in the north and south Phase 2 Overall Benefit Areas, augmented with the deployment of 16 Autonomous Recording Units. No Eastern Whip-poor-will were detected within the mine site, but 19 individuals were observed in the mine periphery (of which 11 were territorial breeding males). The north Overall Benefit area had 15 observations, with 12 being territorial breeding males. The south Overall Benefit area had just one observation and no territorial breeding males. In addition, the Acoustic Recording Units detected six (6) Eastern Whip-poor-will in the north Overall Benefit Area, and one in the south.

No nesting activity or evidence of breeding was observed at any of the Barn Swallow nesting structures. Both Bald Eagle nests that were monitored were active, however the nest near Blackhawk was not successful.

A total of sixteen exceedances of the sound threshold occurred between both sound receptor sites, however, these were all determined to be caused by bird song or meteorological events like wind gusts or thunderstorms. All other hourly sound levels remaining below the 50 dBA threshold.

Incidental Species at Risk observations included American White Pelican, Bald Eagle, Common Nighthawk, Barn Swallow, Bobolink and Snapping Turtle.

Four American White Pelicans were found deceased within the mine site in 2022.

This Species at Risk annual monitoring report summarizes the methods and results of Species at Risk monitoring as per Condition 7.0 of the Overall Benefit permit.

1.0 INTRODUCTION

Cerulean Environmental Ltd. (Cerulean) was retained by New Gold Inc. (New Gold) to conduct Species at Risk (SAR) monitoring at Rainy River Mine (RRM) during the 2022 field season in partial fulfillment of requirements of *Endangered Species Act* (ESA) Overall Benefit permit FF-C-001-14.

Eastern Whip-poor-will (*Antrostomus vociferus*) are listed as Threatened provincially and have been recently down-listed to Special Concern federally by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) in December 2022. The species and its habitat are still currently protected provincially.

New Gold was required to complete Phase 1 Eastern-Whip-poor-will monitoring of the mine site and periphery in 2022 as per Condition 6.1 a) and 6.2 (a)-(g), following the schedule outlined in Appendix G of ESA Overall Benefit permit FF-C-001-14. Although Phase 2 monitoring within the Overall Benefit (OB) areas was not required this year, New Gold sought to obtain updated occupancy and distribution data ahead of finalizing the Eastern Whip-poor-will Habitat Management Plan, since the last Phase 2 survey in the OB lands occurred four years earlier in 2018.

Additionally, Barn Swallow (*Hirundo rustica*) and Bald Eagle (*Haliaeetus leucocephalus*) nest monitoring was required per provincial Environmental Assessment (EA) notice of approval Condition 5 outlined in New Gold's Follow-up Monitoring Plan (Amec Foster Wheeler, 2016).

2.0 METHODS

Cerulean completed monitoring for Eastern Whip-poor-will on the mine site, periphery and Overall Benefit Areas, as well as for Bald Eagle and Barn Swallows during two field visits from May 18-22 and June 8-14, 2022.

It is important to note that the winter of 2022 saw record snow accumulations, and the spring freshet was significantly delayed but came on relatively quickly with warm temperatures and unprecedented levels of precipitation in April. The Rainy River Basin received 257mm of rain in April and May, which is twice the average. The International Water Levels Committee of the Rainy-Lake of the Woods Watershed Board noted that widespread historical flooding occurred within the Rainy River Basin, with Rainy Lake reaching record-breaking water levels (IJC 2023). The abnormal spring weather conditions appeared to delay spring migration and the start of the breeding bird window.

2.1 Eastern Whip-poor-will Monitoring

2.1.1 In-Person Surveys

Eastern Whip-poor surveys were completed on the mine site and periphery (Phase 1 monitoring) and in the Overall Benefit Areas (Phase 2 monitoring) following the Draft Survey Protocol for Eastern Whip-poor-will in Ontario (MNRF 2014). Survey stations were 500m metres apart and three rounds of surveys were conducted. Previous surveys completed by Wood from 2015-2018 (Wood 2019) and Northern Bioscience in 2020 (NBS 2021) followed the *Whip-poor-will Roadside Survey Participant's Guide* (BSC

2012) protocol and survey station spacing ranged anywhere from 200-1600m. MECP previously indicated a strong preference for following the provincial survey protocol, and because the goal of Phase 1 and 2 monitoring is to accurately assess occupancy and distribution, the survey stations were revised to have a consistent 500m spacing. Fifty (50) survey stations were completed within the mine site and periphery (Phase 1) and 48 in the OB areas (Figure 2, Appendix A). In 2018, Wood surveyed 24 and 77 Phase 1 and Phase 2 monitoring stations, respectively.

Surveys were conducted by experienced avian biologists within a week on either side of the full moon within the survey window of May 18-June 30 on calm, nights, with little cloud cover and no precipitation. The first round of surveys was completed from May 18-21, the second from June 8-10 and the third round from June 11-13.

Surveys lasted 5 minutes and began 30 minutes after sunset and continued until roughly midnight or 01:00. Survey location (UTM), start and end time, and habitat description was recorded. Environmental conditions (air temperature, wind, cloud cover, moon visibility and natural or anthropogenic noise disturbance were noted. Common Nighthawk (*Chordeiles minor*) (Special Concern) were recorded, as well as other bird song and amphibian species.

The number of Eastern Whip-poor-will, direction and distance were estimated, and where access allowed, triangulation efforts were made to determine a more accurate and precise location of the singing male within its territory.

Raw data was spatially analyzed to determine the number of territorial males and the centroid of each individual's location based on triangulation distances and directions. From this process, the number of unique individuals and their core territories could be mapped to determine the number of territorial males over each of the three rounds of surveys.

2.2.2 Autonomous Recording Unit Monitoring

Many of the OB areas are inaccessible by vehicle and require a 500-1500m walk through thick brush in the dark and thus posed a significant health and safety risk. New Gold wanted to determine if unoccupied territories were due to sampling bias due to inaccessibility or poor habitat quality. Although ARUs are unable to ascertain direction from sound, it is possible to determine relative abundance based on the strength and signature of the spectrogram of more than one simultaneously singing males.

The Ministry of Natural Resources and Forestry (MNRF), Environment Climate Change Canada (ECCC) and the Ontario Breeding Bird Atlas (OBBA) use ARUs heavily for abundance monitoring of passerines and nocturnal species. The significant advantage to ARUs is far greater survey effort through consistent daily sampling throughout the breeding survey window regardless of environmental conditions, instead of only 2 or 3 sample points of 5 minutes each from in-person surveys. Recent literature from researchers from University of Alberta and ECCC found that the use of ARUs in Eastern Whip-poor-will surveys can improve overall cumulative detection probability compared to in person surveys (Knight et al., 2022).

Wildlife Acoustics Song Meter Mini acoustic recorders with two microphones were programmed to collect six 5-minute recordings starting half an hour after sunset and every hour afterward. A total of sixteen ARUs were deployed within the north and south OB areas. They were deployed from May 20-June 15 and were mounted to trees at breast height in suitable but previously unoccupied habitat (Figure 1, Figures 3-4, Appendix B). Locations were selected to optimize likelihood of Eastern Whip-poor-will detection while lowering noise disturbance from anurans (i.e., frogs and toads) by avoiding direct placement next to wetlands. Date and time of deployment, location (UTM), and habitat description were recorded, and photos were taken to record ARU placement and surrounding habitat.

Acoustic data was interpreted using Wildlife Acoustic's Kaleidoscope Pro analysis software to detect Eastern Whip-poor-will vocalizations audially and by spectrogram signature. In addition to manual interpretation a cluster analysis was completed of a subset of files. The number of EWPW were recorded (i.e., two individuals calling simultaneously and different strength spectrograms) and estimated distance (0-100m and 100-500m).

Figure 1. Autonomous Recording Unit (ARU) 07 (above) and 10 (below) deployed May 21, 2022.

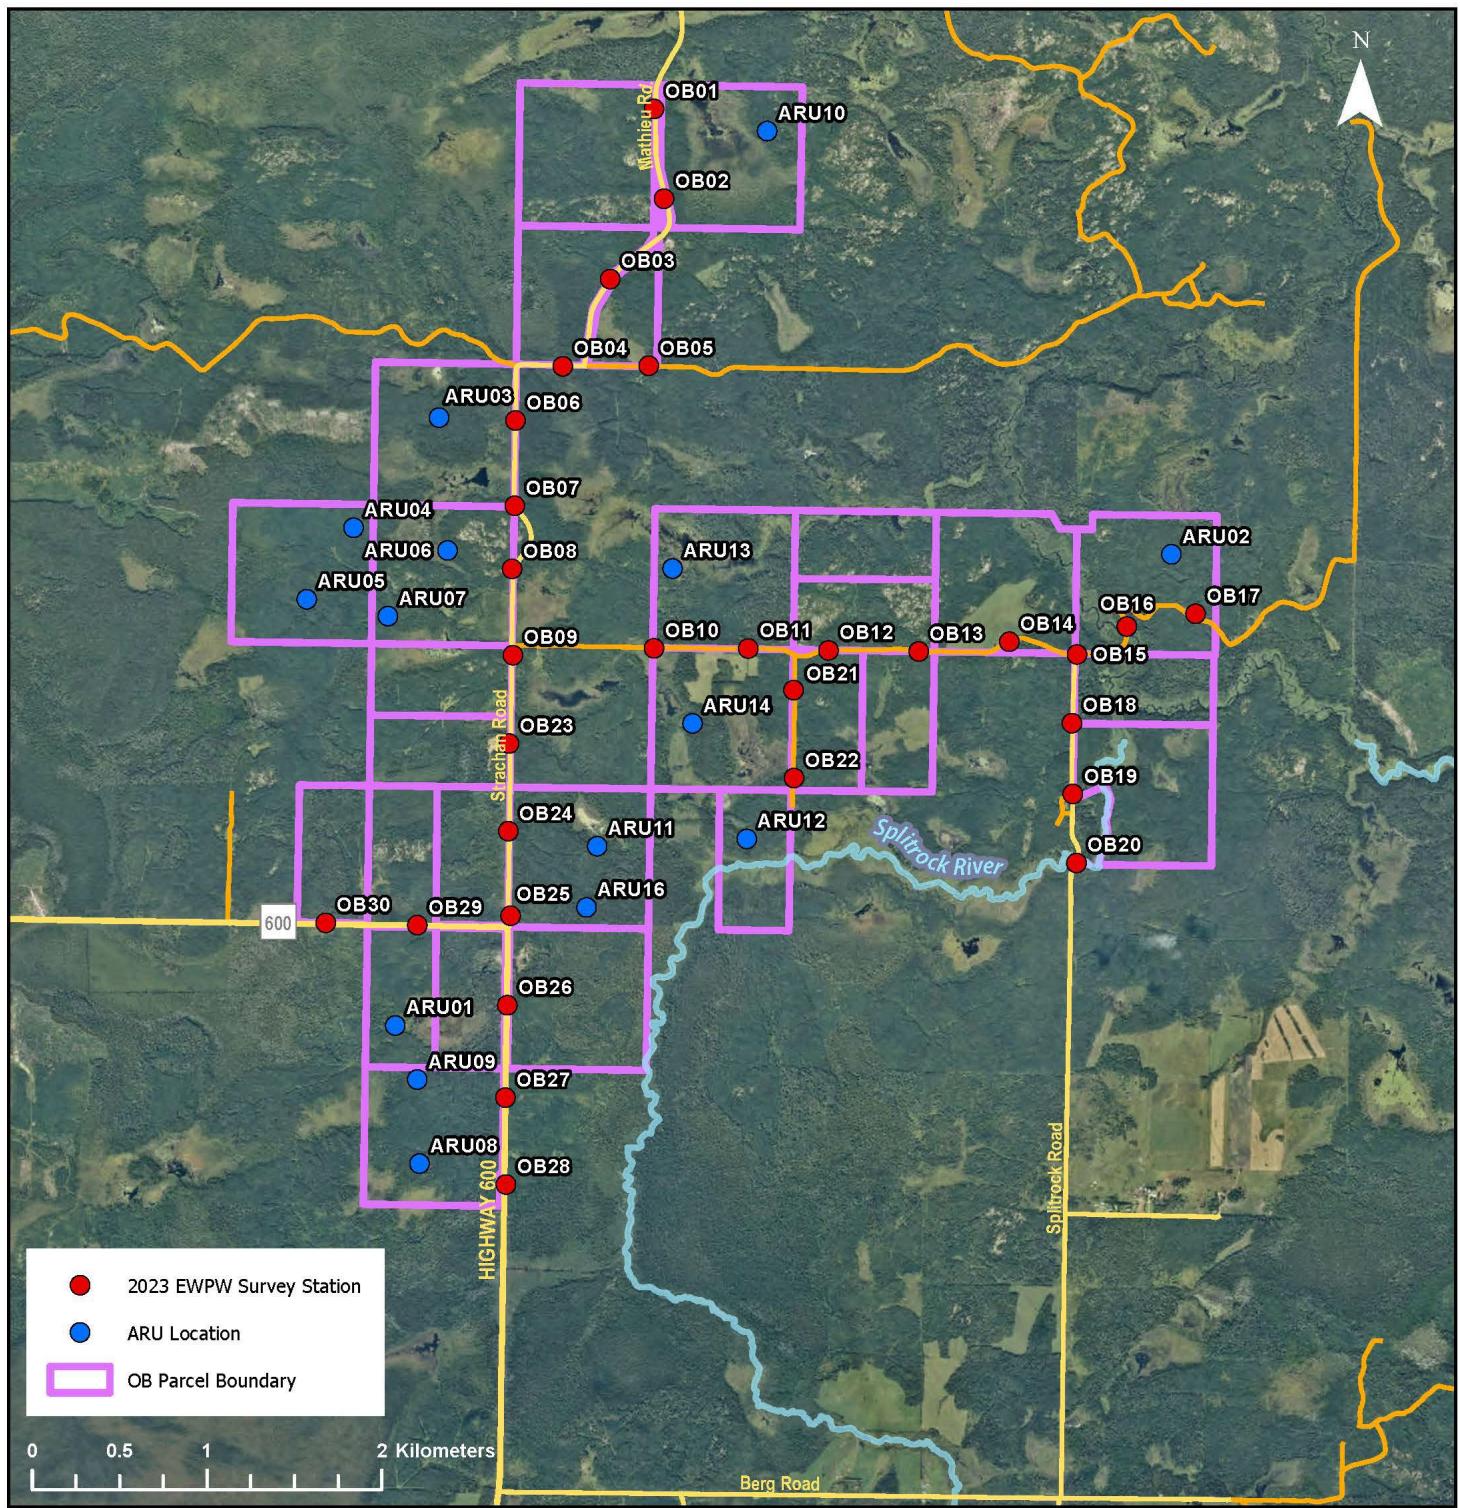

Figure 3. Phase 2 North OB Area Eastern Whip-poor-will survey stations and ARU locations, 2022.

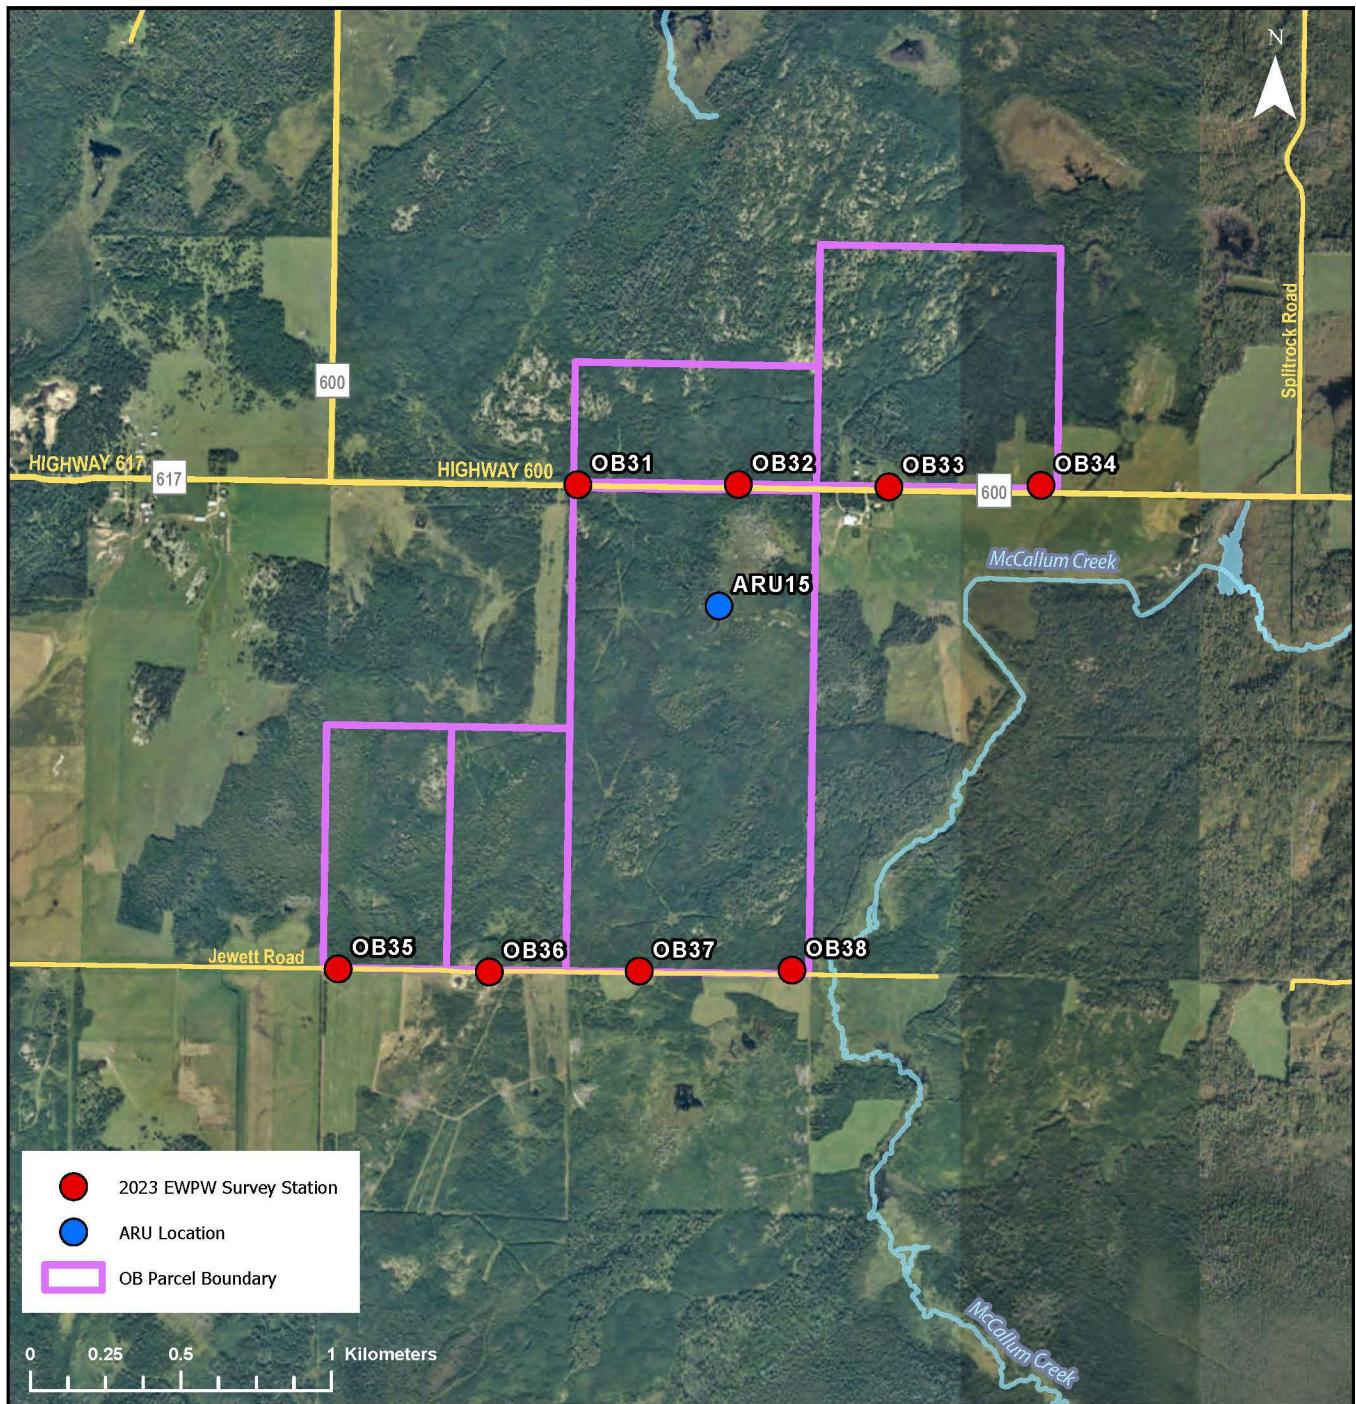

Figure 4. Phase 2 South OB Area Eastern Whip-poor-will survey stations and ARU locations, 2022.

2.3 Bald Eagle Nest Monitoring

All known Bald Eagle nests are required to be monitored to determine annual and seasonal activity at the nest site and to determine fledging success as per provincial EA notice of approval Condition 5 outlined in New Gold's Follow-up Monitoring Plan (Amec Foster Wheeler, 2016).

Monitoring of two known Bald Eagle (Special Concern) nests was completed to determine presence of breeding activity and nest success. These nests are located on Jones Road and Highway 600 west of the mine site (Figure 5). Cerulean biologists visited the nests on May 19, June 10 and 11 and observed the nest and surrounding area to determine nest occupancy and breeding behaviour (presence of nestlings, adults carrying prey, etc.) Environmental conditions such as air temperature, wind and cloud cover were also recorded. Monitoring was completed for one hour each visit using binoculars and a spotting scope.

2.4 Barn Swallow Monitoring

Four Barn Swallow (Threatened) nest structures surrounding the mine site were monitored to determine occupancy, nest density and fledging success and breeding success as per provincial EA notice of approval Condition 5 in New Gold's Follow-up Monitoring Plan (Amec Foster Wheeler, 2016) on May 29 and June 10 (Figure 5, Appendix C). Cerulean biologists observed the nest structures and surrounding area with binoculars and a spotting scope for at least 30 minutes. The nest structures were then visually inspected for evidence of nesting (nesting material, eggs, feces, feathers) and of predation using a small, handheld, telescoping mirror. Environmental conditions such as air temperature, wind and cloud cover were also recorded. New Gold environmental staff also performed nest monitoring following the same protocol on May 30, June 21 and August 20.

Figure 5. Bald Eagle and Barn Swallow nest monitoring locations, 2022.

2.5 Eastern Whip-poor-will Sound Monitoring

New Gold RRM is required to conduct sound monitoring the first week of May and in June during each year of operations to conduct acoustic audit measurements per ESA permit Condition 4.2 (b) and 6.2 (c). The purpose of the sound monitoring is to determine if sound levels produced by operations exceed the sound level threshold as defined as 50 dBA during a one-hour period.

Sound monitoring was completed by Independent Environmental Consultants (IEC) during June 16-25 and June 25-July 4. Sound monitoring was delayed and did not occur in the May timing window due to the late spring freshet, high run-off and wet ground conditions. Due to late start to passerine breeding in 2022 and given that early July is still within the breeding period for Eastern Whip-poor-will (MECP, 2014), sampling in this later window should be adequate to address potential effect on EWPW. Levels were measured at two Eastern Whip-poor-will Receptor Habitats that have the highest predicted sound levels both north and south of the mine site (NM-1 and NM-2 respectively). Due to memory writing issues, data for the second data collection period at NM-2 was not available for analysis.

Sound levels were measured on a continuous 15-minute basis throughout the measurement program, using Larson Davis 831C sound level meters. To assist in the analysis, the meters were also configured with an “event trigger” that provided more detailed sound level information in instances where sound

levels above 50 dBA were measured. This included sound recording to assist with identifying the source of noise that caused the sound level of 50 dBA to be exceeded (though it should be noted that an instantaneous exceedance of 50 dBA does not necessarily mean that the energy equivalent for the entire hour will exceed 50 dBA). In instances where adverse meteorological conditions, or sounds of nature (e.g., birdsong) were found to have caused the elevated sound levels, the associated data point was discarded as unrepresentative of sound from operations at the mine site.

For detailed methodology, see Appendix G “IEC 2022 Sound Monitoring Report: Eastern Whip-poor-will Habitat New Gold Inc. (IEC, 2022).

2.6 Other Species at Risk Observations

New Gold RRM is required to document all incidental SAR observations annually. Cerulean biologists also documented incidental SAR observations during fieldwork in 2022 and a summary of both is provided in Section 3.6.

2.7 Mortality Events Reporting

As per ESA permit Condition 7.3 (k), New Gold is required to document any mortality events occurring within the project site or OB areas. If applicable, adaptive management strategies are to be outlined to reduce mortality within the OB areas. New Gold tracks all mortality events and these events from 2022 are reported in Appendix H.

2.8 Species at Risk Training

Species at Risk training is required for all staff and contactors who work on site (specifically the OB areas) as per Condition 4.3 (a) of the Overall Benefit permit. Training emphasizes educating personnel about the purpose of the OB areas, the permit and its conditions, as well as mitigating harm to the species and damaging or destroying habitat. As per the ESA permit reporting requirements (Condition 4.3 (b)), a complete summary of SAR awareness training provided in 2022 indicating the names of personnel trained, education material covered, date of training and method of training is provided in Appendix I.

2.9 Equipment Operating Hours Monitoring

Operations at Rainy River Mine in 2022 included blasting, loading, hauling, dumping, crushing, milling rock placement, and dam construction. Vehicle and equipment operating time is recorded for each piece of equipment by on-board GPS and operator hour recordings. A summary of equipment operating hours is tabulated in Section 3.9.

3.0 RESULTS

The winter of 2021/2022 had unseasonably large amounts of snow causing a delayed spring. This was followed by heavy precipitation and a fast melt, causing widespread flooding. Cerulean biologists noted that this delayed the spring songbird migration across northern Ontario by roughly 2-3 weeks. The saturated ground, and amount of surface water run-off likely affected the timing of migration and start

of the breeding period for Eastern Whip-poor-will. This unprecedented flooding in the Rainy River Basin added another variable to comparisons of previous years' population data.

3.1 Eastern Whip-poor-will Monitoring within the Mine Site and Periphery (Phase 1)

No Eastern Whip-poor-will were detected within the mine site on any three rounds of surveys, but 19 individuals were observed in the mine periphery (with 31 total observations). Eleven of the individuals were territorial breeding males as they were heard singing within a distinct territory during more than one visit during the breeding season. Results are displayed in Table 2 and 3, Figure 6 and summarized in Appendix D and Appendix E.

Eastern Whip-poor-will numbers have declined on the mine site, since 2020 when eight observations were reported. However, numbers in the periphery have increased from six in 2020 to 19 individuals in 2022. Eleven territorial breeding males were mapped in the mine periphery in 2022. It is possible that individuals displaced or disturbed by mine operations have relocated to suitable habitats in the mine periphery.

Table 2. Summary of Phase 1 mine site and periphery Eastern Whip-poor-will observations per visit.

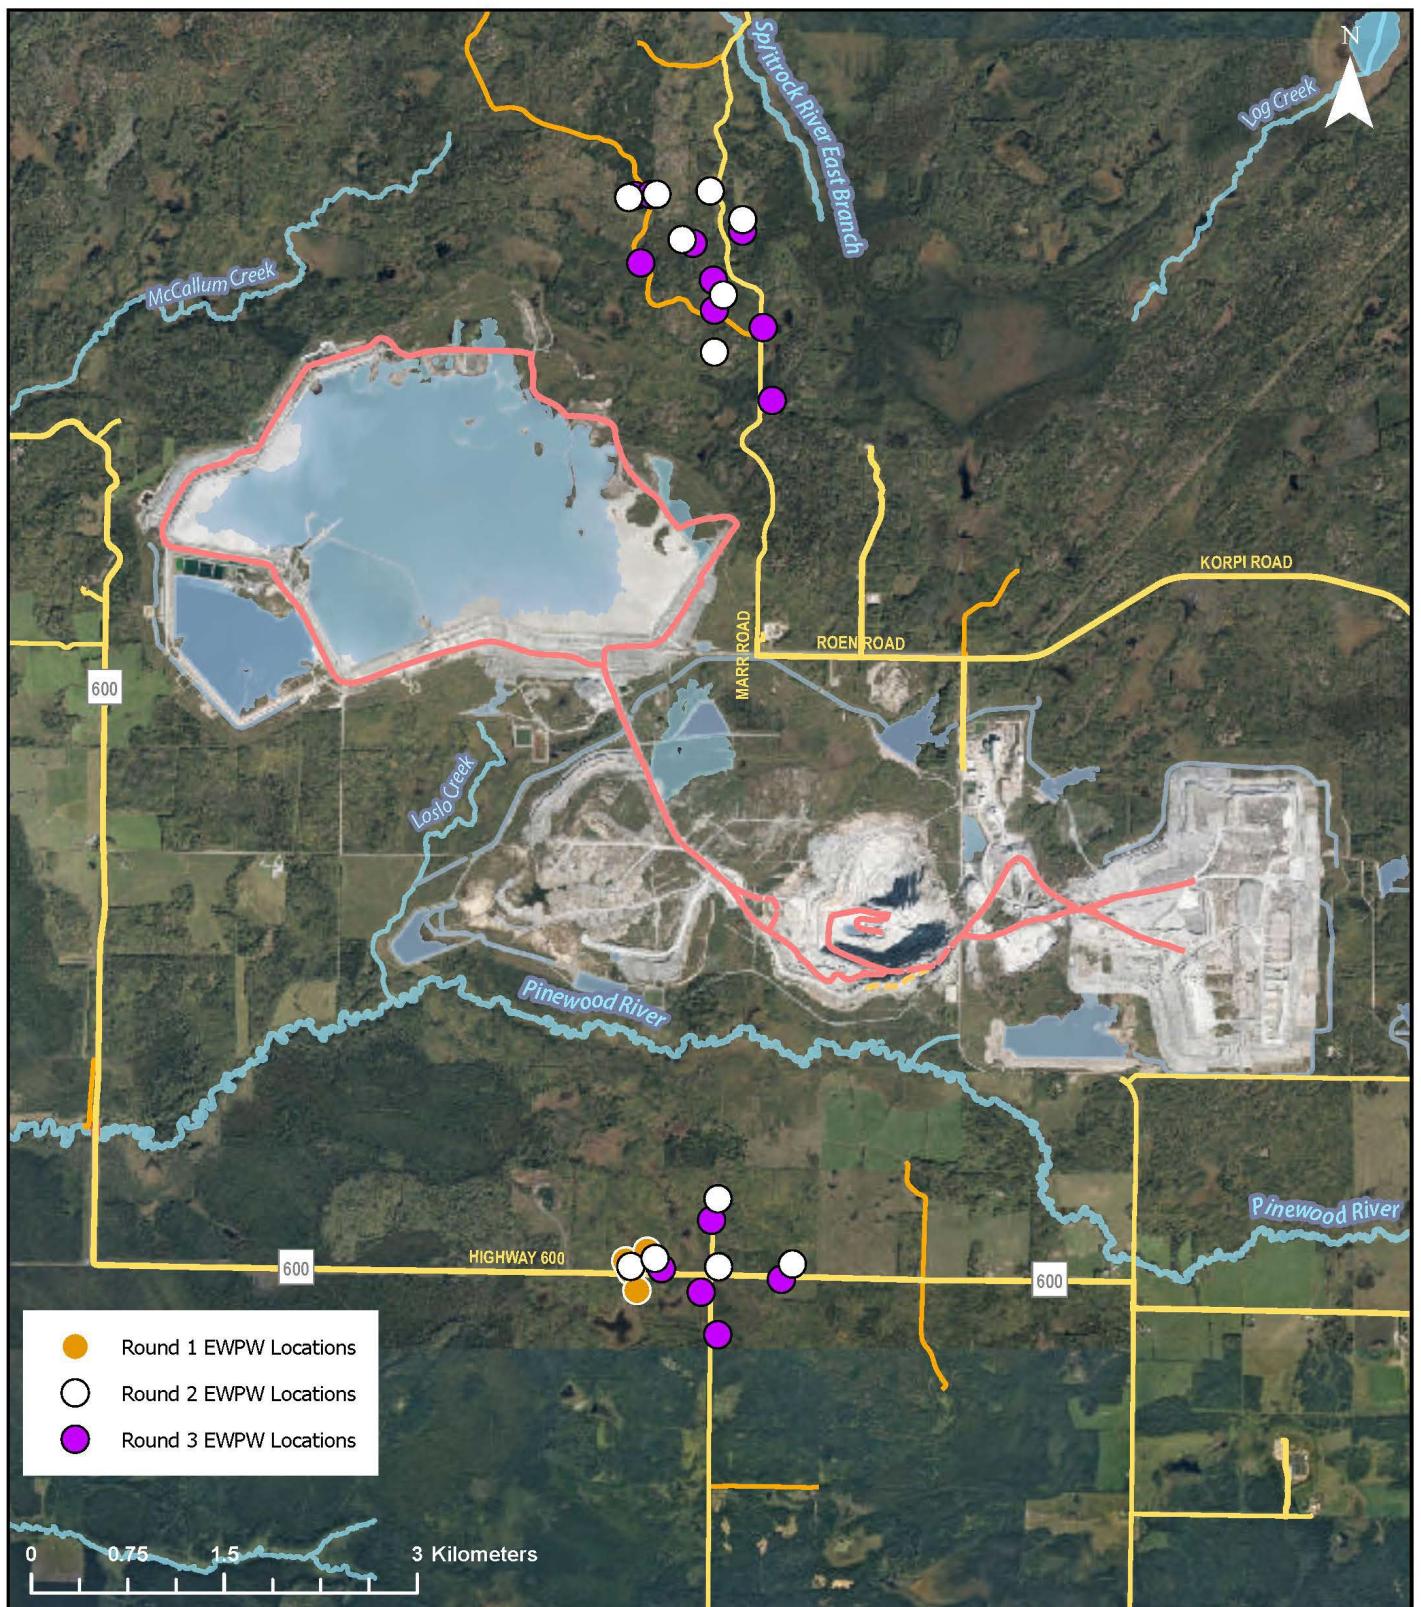

Figure 6. Phase 1 mine site and periphery Eastern Whip-poor-will observations, 2022.

3.2 Eastern Whip-poor-will Monitoring within the Overall Benefit Areas (Phase 2)

3.2.1 In-person Surveys

Fifteen (15) Eastern Whip-poor-will observations were recorded in the north OB area during three rounds of surveys; with 12 being territorial breeding males. The south OB area had just one observation and no territorial breeding males. Survey results are summarized in Table 4 and 5, Figure 7, 8 and 9, Appendix D and E.

Making a direct comparison to occupancy and distribution from the previous survey period in 2018 is difficult because of the change in survey methodology. As noted in Section 2.1, in 2018 77 in-person survey stations were completed compared to 48 in 2022 due to accessibility issues. On numerous occasions, despite ideal survey conditions and timing, males sang for mere seconds during the survey period; so, it is possible that individuals were underrepresented. Regardless, 12 territorial breeding males were mapped in 2022, compared to 15 in 2018.

Table 4. Summary of Phase 2 mine site and periphery Eastern Whip-poor-will in-person observations per visit.

EWPW Station	Round 1	Round 2	Round 3
OB02	0	1	0
OB13	1	1	1
OB14	0	2	2
OB16	0	1	1

OB30	0	0	0
OB33	0	0	1

Table 5. Summary of in-person Phase 2 North and South OB Areas Eastern Whip-poor-will observations and breeding territories.

Number of EWPW Observed in OB Areas (Phase 2) in Person Monitoring					
	2015	2016	2017	2018	2022
Northern OB	11	27	29	43	15
Total Breeding Territories	n/a	n/a	n/a	15	12
<hr/>					
Southern OB	11	12	10	10	1
Total Breeding Territories	n/a	n/a	n/a	6	0

3.2.2 Autonomous Recording Units

Eastern Whip-poor-will were detected at seven of the 16 ARUs; six in the northern OB area and one in the south OB area (Figure 8 and 9). A complete summary of detections is outlined in Appendix F. These areas had been unoccupied by Eastern Whip-poor-will during all previous surveys. Although determination of exact locations are not possible from ARUs due to inability to estimate direction, it can be concluded that for a strong spectrogram, a singing territorial male is located within approximately 100m radius of the ARU location whereas a weak spectrogram indicates a male within a 100-500m radius. An example of an Eastern Whip-poor-will spectrogram is depicted in Figure 7. The song generally ranges from 1.8-2.8 kHz (not be confused with Spring peepers (*Pseudacris crucifer*) or Gray tree frog (*Dryophytes versicolor*) which is visible at the 2.8-3.4kHz and 1.8-2.2kHz respectively.

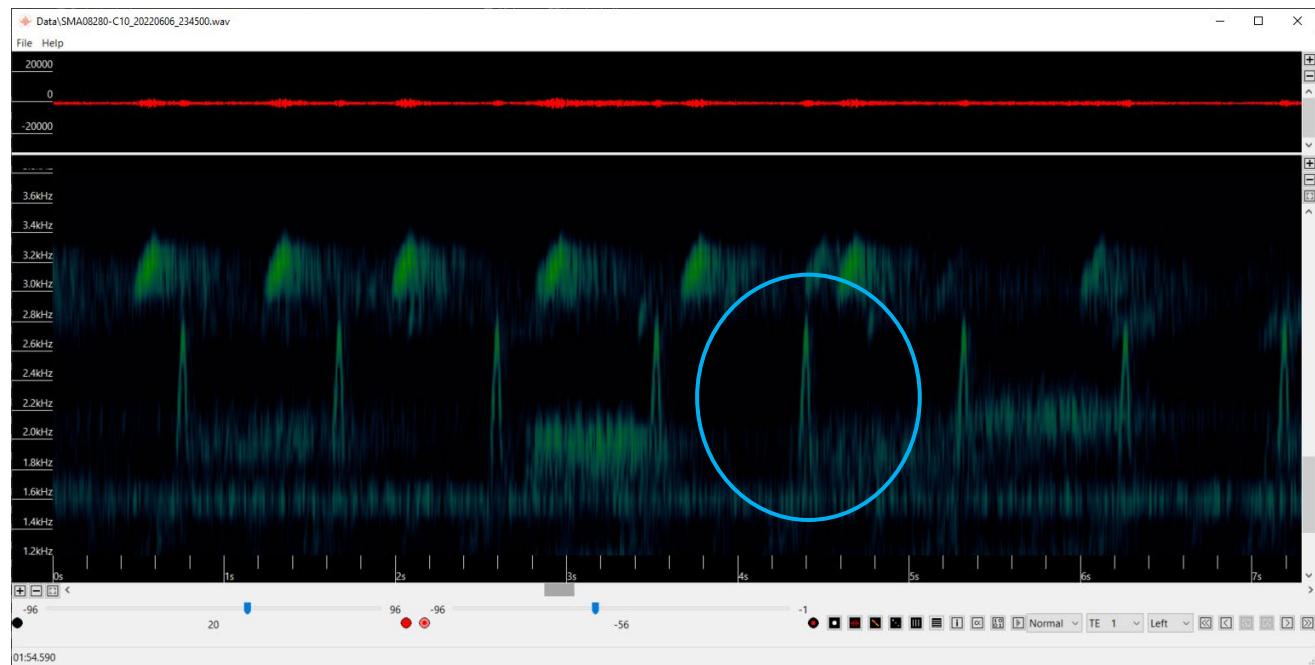

Figure 7. Eastern whip-poor-will spectrogram (1.8-2.8kHz) at ARU 10 in North OB Area, June 6, 2022 at 23:45.

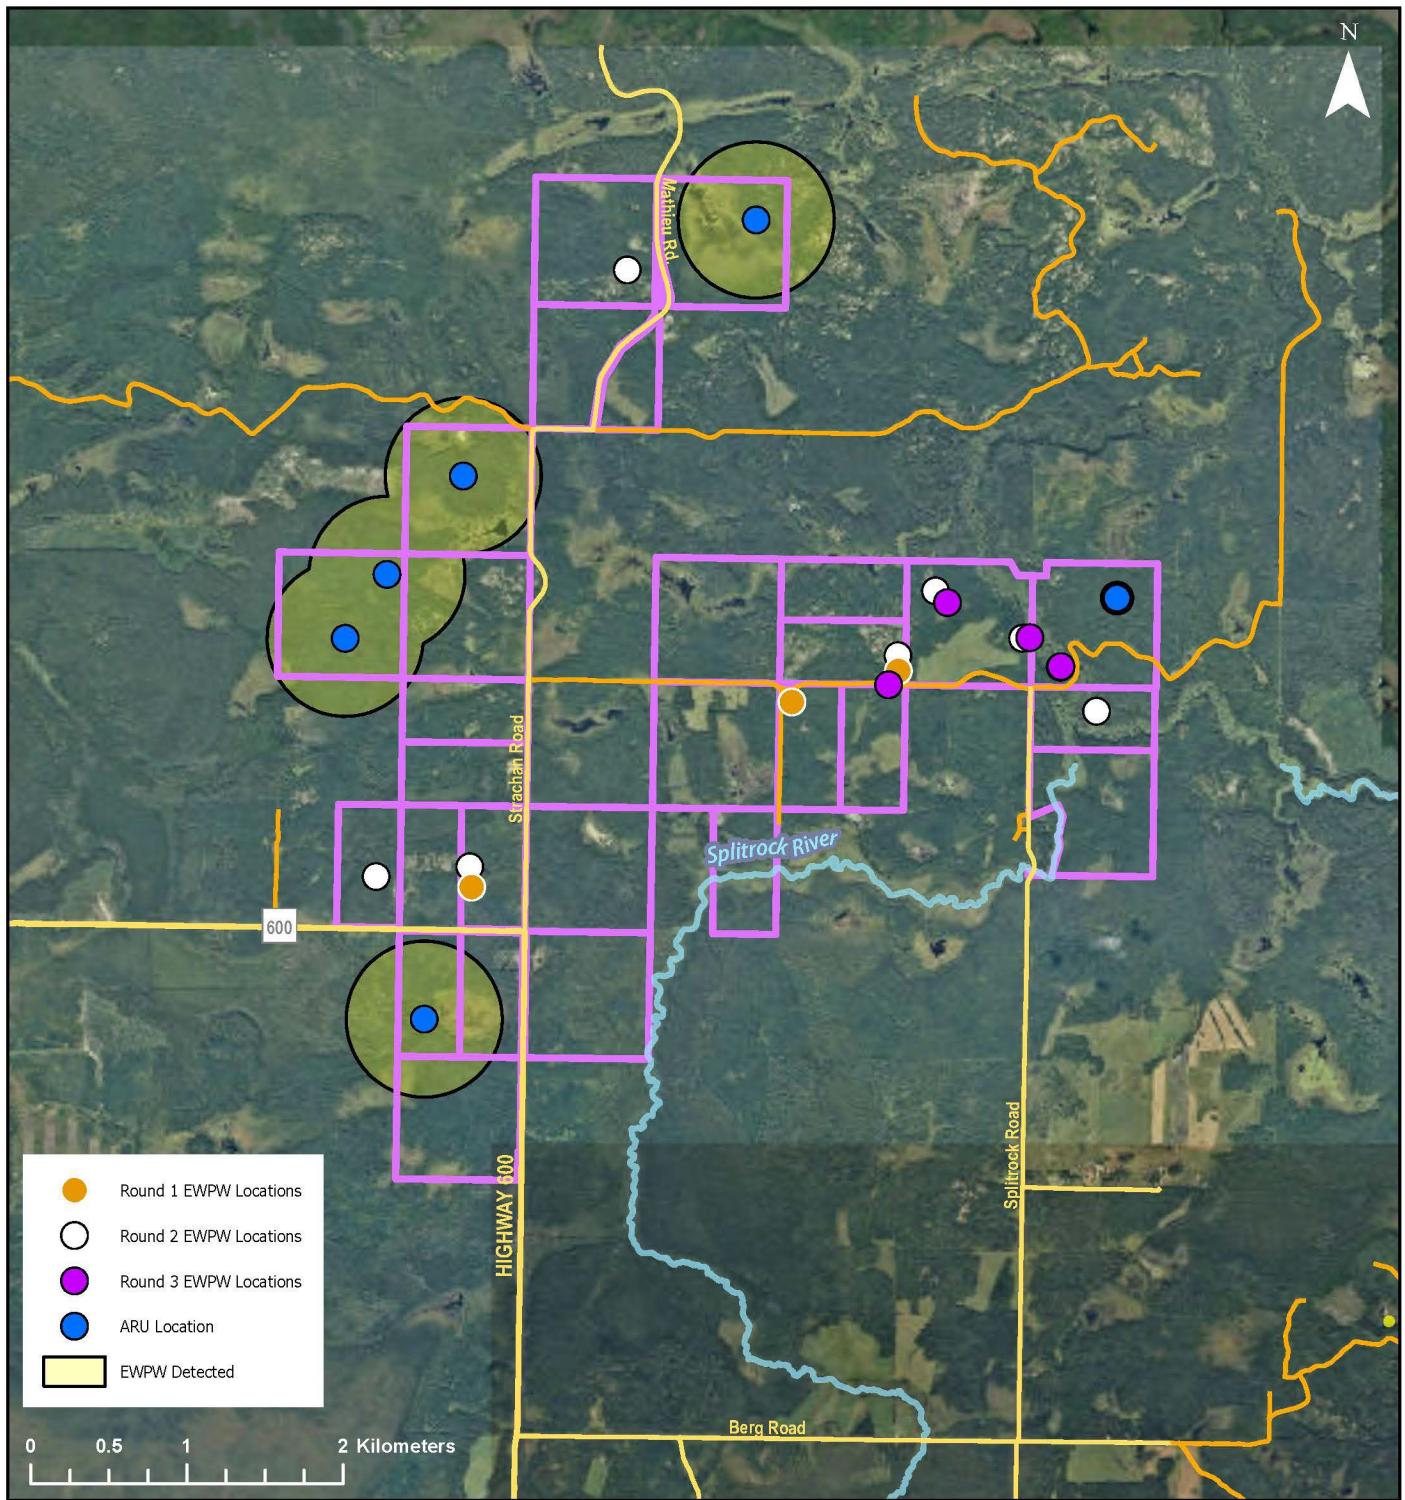

Figure 8. Phase 2 North OB Area Eastern Whip-poor-will observations, 2022.

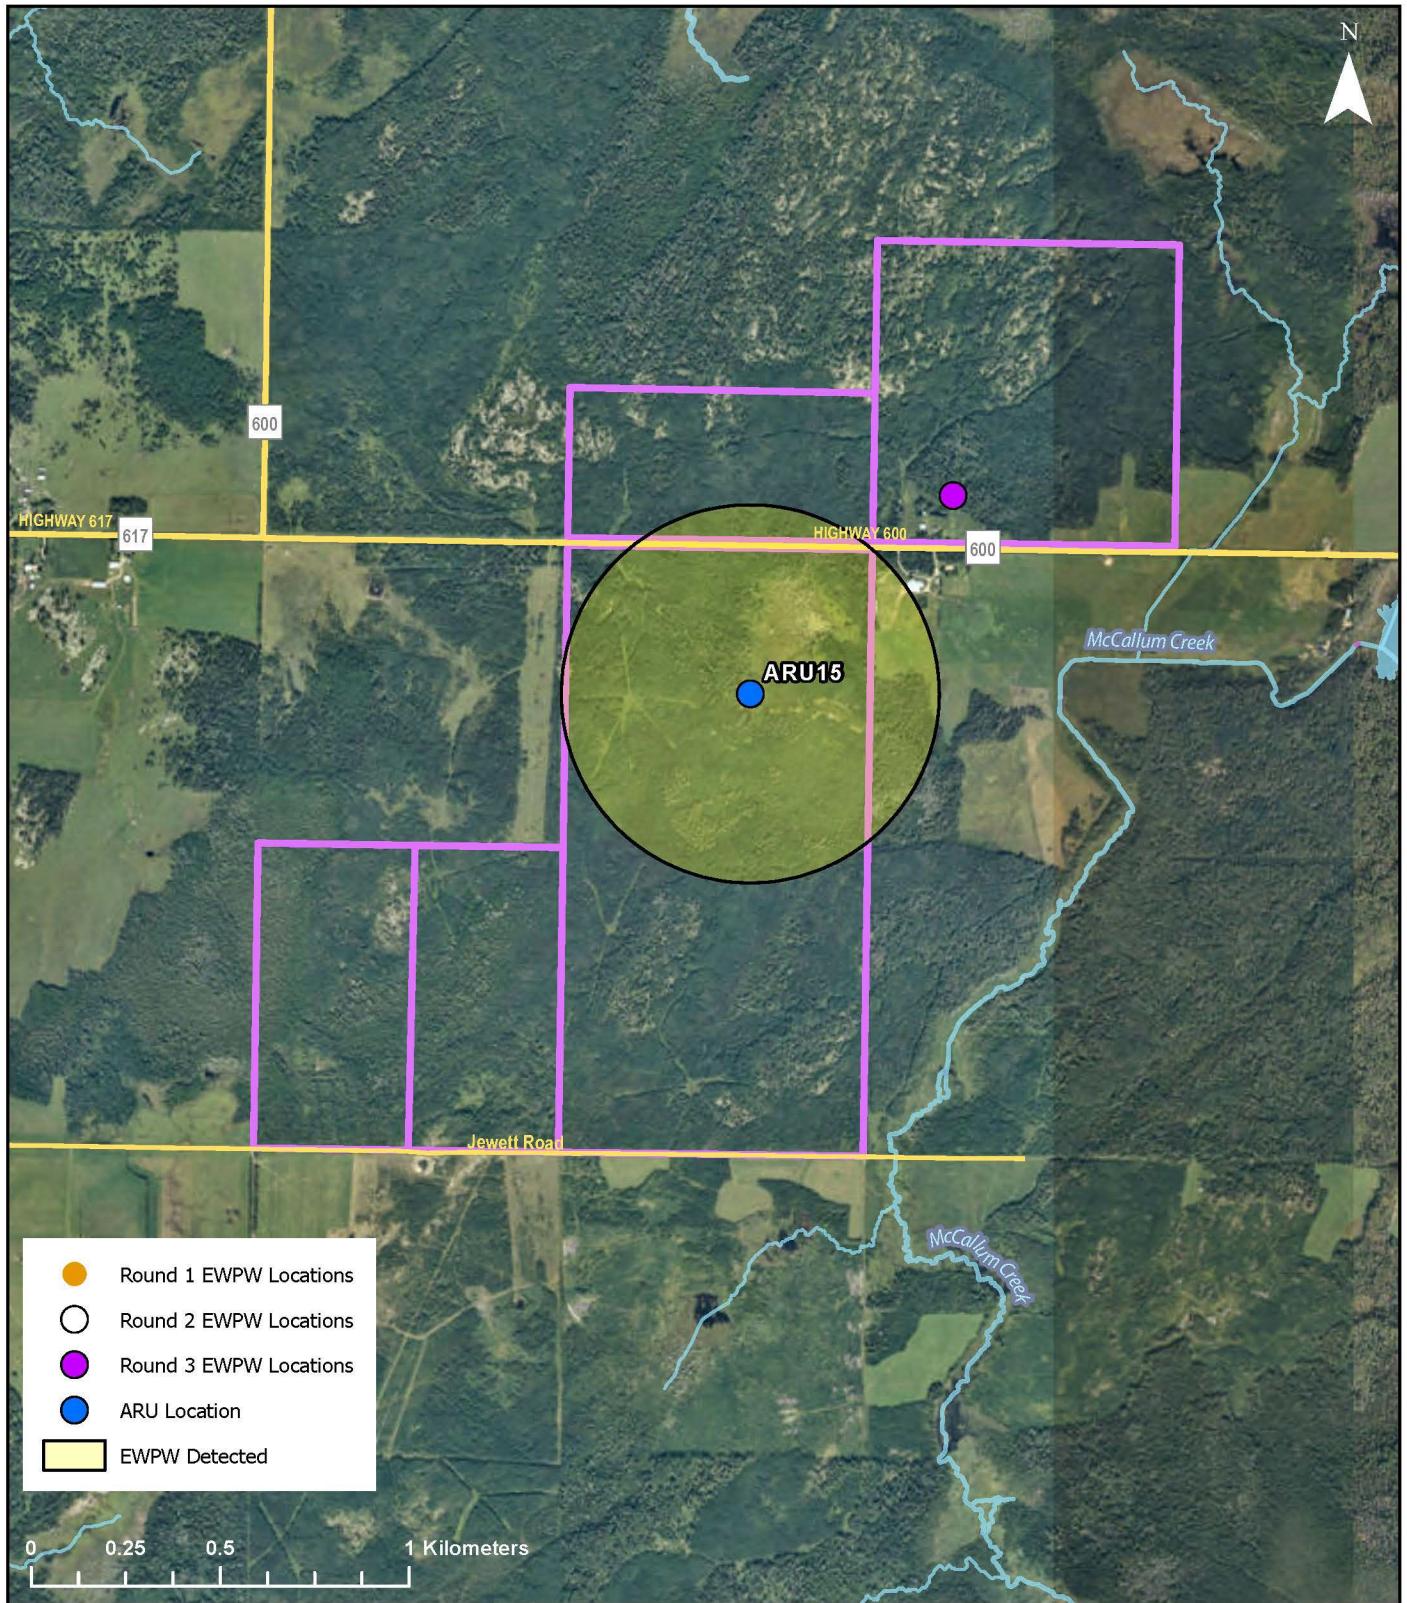

Figure 9. Phase 1 South OB Eastern Whip-poor-will observations, 2022.

3.3 Bald Eagle Nest Monitoring

Biologists observed an adult Bald Eagle feeding an unknown prey item to one small white downy nestling on May 19 at Bald Eagle nest 1 at Blackhawk (Figure 10). On June 10, one nestling was observed in the nest, with one adult perched nearby.

Two adults were observed on the Jones Road nest (Bald Eagle nest 2) together on May 19, presumed to be taking turns incubating (Figure 11). No prey items were brought to the nest during the observation, so it is likely the nest was at the incubation stage. On June 11 no activity or Bald Eagles were observed on the nest or in the surrounding area during the one-hour monitoring period. We suspect that the nest failed or was predated.

Figure 10. Bald Eagle feeding nestling at Bald Eagle nest 1. May 19, 2022 (photo by A. Spenceley).

Figure 11. Active Bald Eagle nest 2 on Jones Rd May 19, 2022 (photo by A. Spenceley).

3.4 Barn Swallow Monitoring

No evidence of breeding by Barn Swallows was observed at any of the nest structures during 2022 monitoring efforts. Four Barn Swallows were observed foraging overhead at nesting structure A but were likely nesting in adjacent barns to the east and did not go into the nesting structure. At nesting structure C, nest cups were empty except one cup, which contained a loose collection of grass and moss, likely from an Eastern Phoebe. Two Barn Swallows were seen foraging in the general area of nest structure D but didn't go into the nest structure. Five unoccupied and inactive Barn Swallow nests were seen in the garage (one containing 3 old eggs from last year) near structure D and there was one inactive nest in a nearby shed (Figure 12).

Figure 12. Inactive Barn Swallow nests in shed and garage near nest structure D May 19, 2022 (photos by A. Spenceley).

3.5 Eastern Whip-poor-will Sound Monitoring

A total of nine out of 141 hours were in excess of the 50 dBA threshold at the NM-1 location after the meteorological validation step during campaign #1 (the instrument did not log data in campaign #2). At NM-2, a total of seven hours out of the 276 hours of valid data (inclusive of both campaigns) were in excess of the 50 dBA threshold after the meteorological validation step. Sound recordings for each of these hours were reviewed to determine whether the operations at the Rainy River Mine were audible; however, in each instance the dominant sound was either bird calls which appeared to be sounding very close to the microphones, wind gusts, or presence of thunder prior to rain events. As such, these hours were removed from the data set as they were not representative of Rainy River Mine operations. This resulted in all other hourly sound levels remaining below the 50 dBA threshold.

For complete results and discussion of the sound monitoring see Appendix G “IEC 2022 Sound Monitoring Report: Eastern Whip-poor-will Habitat New Gold Inc.”

3.6 Incidental SAR Observations

To support the monitoring of SAR species onsite, the Environmental Department implemented a site wide protocol for reporting wildlife in 2015. Through this system the following SAR sightings were reported by New Gold staff and contractors in 2022; 5 Bobolink, 13 Barn Swallow, 32 Bald Eagle, 68merican White Pelicans, 105 Bank Swallows and, 1 Snapping turtle.

In addition to on site reporting completed by New Gold, Cerulean staff also documented incidental SAR observations while on the project site and OB areas during field work conducted May 18-22 and June 8-14:

- Fifteen American White Pelican (listed Threatened provincially) flew over the mine site on May 18 and 19.
- Three adult and one nestling Bald Eagle (listed as Special Concern provincially) were observed during monitoring of two known nests (see section 3.4).
- Thirteen Common Nighthawk (listed as Special concern provincially and federally) were recorded during Eastern-Whip-poor-will surveys conducted from May 18-21 and June 8-13.
- Twelve Barn Swallows (listed as Threatened provincially and federally) were seen foraging or flying in the mine periphery May 19 and June 10.
- Four Bobolink (listed as Threatened provincially and federally) observed or heard in the site periphery on May 19, May 22 and June 10.

3.7 Mortality Events

Four American White Pelicans (listed as Threatened provincially) were found deceased on the project site in 2022. One was found on the Clark Creek Dam July 28th. Three were found between June 10th and 11th on site dams and seepage ponds. All mortalities were reported to MECP within 24 hours and instruction was given to test for avian flu H5N1. One individual was sent to the Canadian Wildlife Health Co-operative and tested positive for H5N1 (see lab report in Appendix H). MECP direction was to assume all American White Pelican mortalities were a result of the avian flu. A complete list of mortality events at the mine is detailed in Appendix I.

3.8 Species at Risk Training

A complete list of Species at Risk training provided to staff and contractors during 2022 is outlined in Appendix J.

3.9 Equipment Operating Hours

The equipment operating hours for heavy machinery in 2022 are summarized in Appendix K

APPENDICES

Appendix A: Sound Level Data Tables

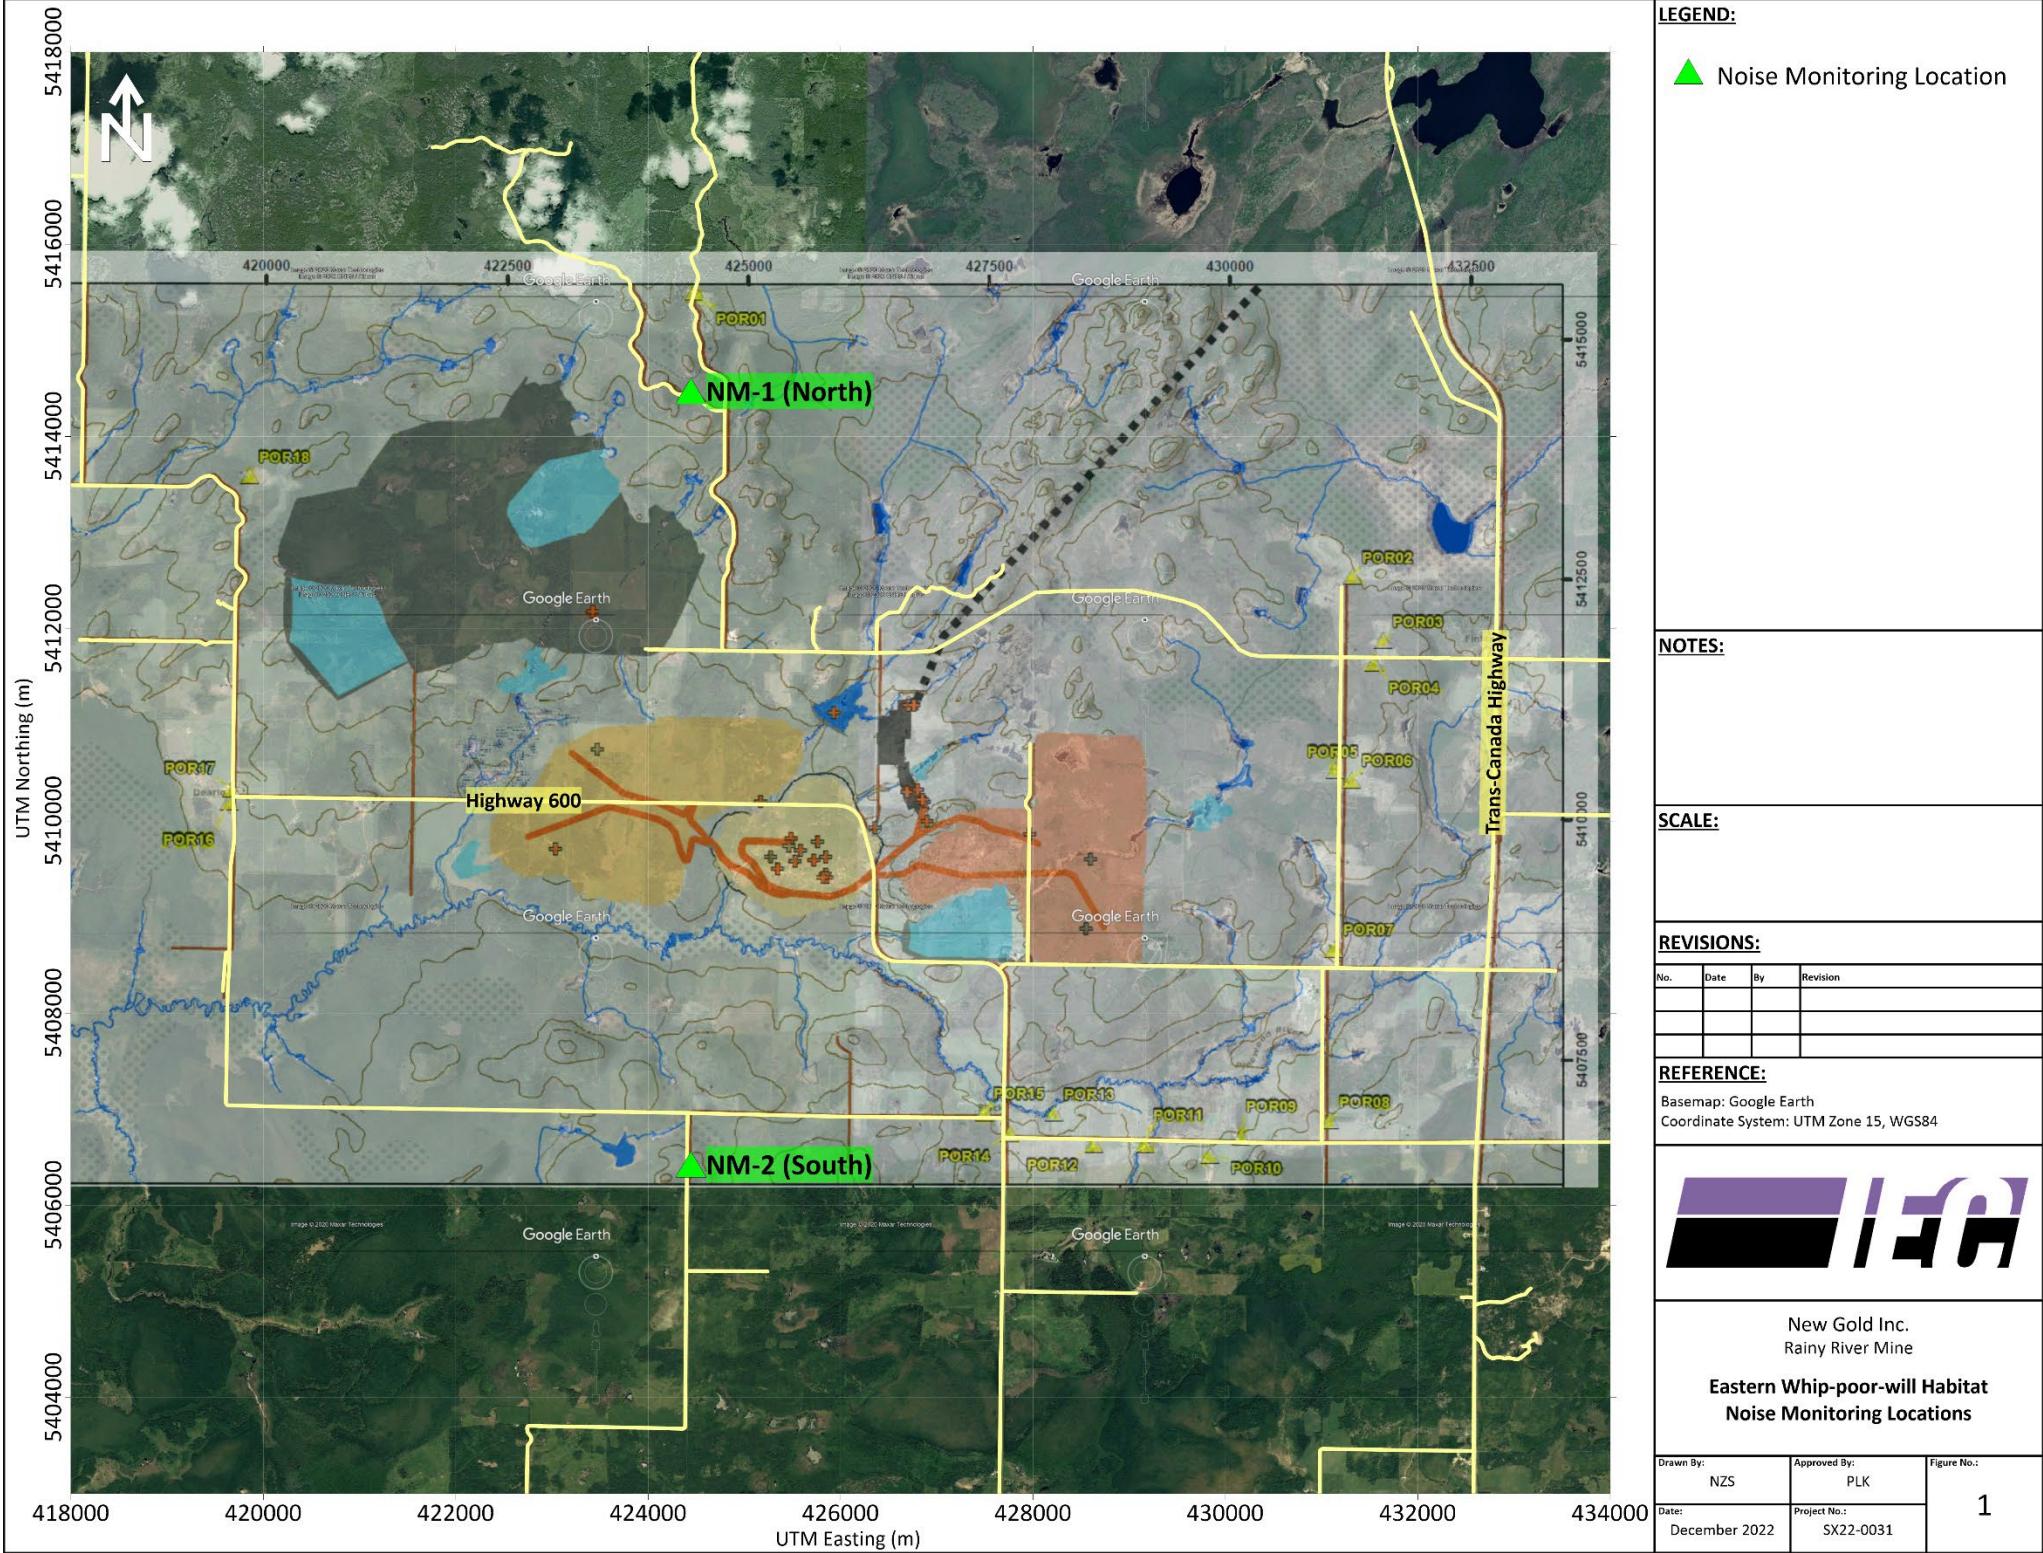

INTRODUCTION

Independent Environmental Consultants (IEC) was retained by New Gold Inc. to assist in the completion of an ambient sound monitoring study in the vicinity of the Rainy River Mine. This is part of an acoustic auditing program that is required under the *Endangered Species Act*, as stipulated by the Ontario Ministry of Natural Resources and Forestry (MNRF) in an *Overall Benefits Permit* issued to the New Gold Rainy River Mine (Permit No. FF-C-001-14). The permit is now controlled by the Ontario Ministry of Environment, Conservation and Parks (MECP). In accordance with the permit, sound level monitoring is to take place at locations identified as known habitat for Eastern Whip-poor-will (*Antrostomus vociferus*). This report provides an overview of the operations at the Rainy River Mine site, details of the surrounding area, MECP requirements pertaining to the Eastern Whip-poor-will habitat sound monitoring program, as well as details and results of the monitoring program.

SITE AND SURROUNDING AREA

The Rainy River Mine is located approximately 65 km northwest of Fort Frances in northwestern Ontario and consists of an open-pit and underground mine as well as an ore processing facility located on-site. Other site infrastructure includes the tailings management area, various stockpiles (e.g., overburden, waste rock), on-site roads for access and haulage of ore material, and buildings for supporting operations (e.g., administration, maintenance). Operations at the site in 2022 included blasting, dam construction, crushing, loading, hauling, dumping, and rock placement.

The lands surrounding the mine site are generally forested areas, with some farmlands throughout. Of particular relevance to this study is the presence of an Eastern Whip-poor-will habitat adjacent to the mine lands. The Eastern Whip-poor-will are considered a Threatened Species per *Ontario Regulation 230/08* under the *Endangered Species Act* and are known to be particularly sensitive to noise. With regards to sources of noise that are present in the area other than those associated with mine operations, it should be noted that there are several highways in the area including the Trans-Canada Highway, Highway 600, and Highway 617. There is also a CN rail line located approximately 16 km to the south of the Eastern Whip-poor-will habitat. Refer to Figure 1 for an illustration of the site location in relation to the relevant features of the surrounding area.

REGULATORY CONTEXT

As noted previously, there is an Eastern Whip-poor-will habitat adjacent to the mine lands, which have been identified by the MNRF as a Threatened Species. As a result, the MNRF have issued an *Overall Benefits Permit* (No. FF-C-001-14), which is now controlled by the MECP, to New Gold for the Rainy River Mine. This permit outlines measures for the protection of this species. Included in the permit is a requirement to complete periodic acoustic monitoring at the Eastern Whip-poor-will habitat and determine whether activity at the mine site results in sound levels exceeding 50 dBA (on a 1-hour basis).

The monitoring requirements differ depending on the stage of activity at the site (e.g., construction, operations). During construction activity, the monitoring is required on an annual basis, while during operations the monitoring is to be completed in 2-year intervals. As noted in Section 2.0, the mine was in the Operations stage at the time that the monitoring was completed. It should be noted that the permit stipulates that acoustic monitoring is to occur in the first week of May as well as in June; however, the timing for the 2022 acoustic audit was delayed. The sound monitoring data discussed in this report was collected in the June measurement window and continued into the beginning of July. According to the MECP, the nesting season of the Eastern Whip-poor-will may extend from mid-May to the end of July (1).

MEASUREMENT PROGRAM

The sound level measurement campaigns were completed over the following periods:

- June 16th to June 25th, 2022; and
- June 25th to July 4th, 2022.

As per the requirements of the Permit, the sound monitoring was conducted at two locations, representing the “north” and the “south” Eastern Whip-poor-will habitats (see Figure 1). The north and south monitors are identified as NM-1 and NM-2, respectively, in the discussion in this report and the coordinates are provided in Table 1. Due to a memory write issue, data for the second campaign at NM-1 was not available for analysis. Operationally, there have been no changes at the north end of the site.

Table 6: Noise Monitoring Locations

Monitor ID	Monitor Location	Monitor Coordinates (UTM, Zone 15)	
		Easting (m)	Northing (m)
NM-1	Noise Monitoring Location 1 (North)	424444	5414473
NM-2	Noise Monitoring Location 2 (South)	424444	5406426

The measurement equipment was deployed in the field by New Gold staff, with technical input, guidance and data analysis provided by IEC. The sound level meters were set up in coordination with IEC to configure the meter settings.

Sound levels were measured on a continuous 15-minute basis throughout the measurement program, using Larson Davis 831C sound level meters. To assist in the analysis, the meters were also configured with an “event trigger” that provided more detailed sound level information in instances where sound levels above 50 dBA were measured. This included sound recording to assist with identifying the source of noise that caused the sound level of 50 dBA to be exceeded (though it should be noted that an instantaneous exceedance of 50 dBA does not necessarily mean that the energy equivalent for the entire hour will exceed 50 dBA). In instances where adverse meteorological conditions, or sounds of nature (e.g., birdsong) were found to have caused the

elevated sound levels, the associated data point was discarded as unrepresentative of sound from operations at the mine site.

New Gold operates a meteorological station at the Rainy River site, which collected data concurrently with the sound level meters. As sounds due to certain meteorological events may result in elevated sound levels, ambient noise measurement data is subject to validation to ensure that data points associated with unrepresentative conditions are removed from the analysis. The Ontario MECP outlines requirements for noise monitoring programs, including meteorological considerations, in Publications NPC-102 (2) and NPC-103 (3). In addition, the sound level meter manufacturer also outlines limitations regarding the performance of the instrument under certain meteorological conditions (4). The meteorological conditions that were applied in the validation of the measurement data are summarized in Table 2.

Table 7: Parameters for Meteorological Validation

Meteorological Parameter	Limiting Condition
Temperature	-10°C to +50°C
Relative Humidity	25% to 90%
Wind Speed	<18 km/hr
Precipitation	No precipitation during measurement

Note:
Based on feedback from the equipment supplier, the adjustment for sound levels collected above the ceiling relative humidity level of 90% is relatively insignificant and data would only need to be discarded if there were condensation occurring. As there did not appear to be any anomalous data associated with the sound levels at humidity levels above 90% these points were kept for a more complete data set.

The sound level meters were last factory calibrated to an NIST-traceable standard in October 2020. In addition, the sound level meters were each calibrated in the field before and after the program, using a handheld CAL200 calibration device. The field calibrations did not result in any significant adjustment. The meters were deployed with environmental protection and were sited in accordance with NPC-102/103, which requires that the microphone be located greater than 1 m above the ground and greater than 1 m away from any reflecting surface. The environmental protection included a wind screen equipped with bird spikes (to deter birds from perching on the microphone), and a heated preamplifier to control the effects of humidity. The sound level meter was stored in a weather-proof hard case, with the preamplifier and microphone attached to a tripod via a microphone extension cable from the hard case.

By the completion of the monitoring period, all sound level data and meteorological was compiled and analyzed for comparison to the 50 dBA sound level threshold.

MEASUREMENT RESULTS

Measurements at the two monitoring locations were completed simultaneously in each campaign and were synced such that both monitors were logging data for the same intervals of time. As noted previously, the meters were each configured to log sound levels on a continuous 15-minute basis. This time step allowed for additional information on what was occurring within each hour; however, ultimately the sound levels were log-averaged on an hourly basis for comparison to the meteorological data (for validation) and to the sound threshold of 50 dBA.

The first campaign ran continuously for 9 days, resulting in 221 logged hourly measurements at NM-1, and 218 at NM-2. Upon comparison to the meteorological data set, a total of 70 hours were removed from each station due to rain and/or high winds, leaving approximately 150 hours of valid data at each station. This is well above the minimum number of hours for an ambient noise monitoring study of 48 hours as stipulated by the MECP in its Publication NPC-300. The second campaign ran for 9 days, resulting in 218 logged hourly measurements at NM-2 (as discussed previously, the data at NM-1 was not logged due to a memory write failure). The meteorological validation resulted in 79 hours being discarded, resulting in 139 hours of valid data.

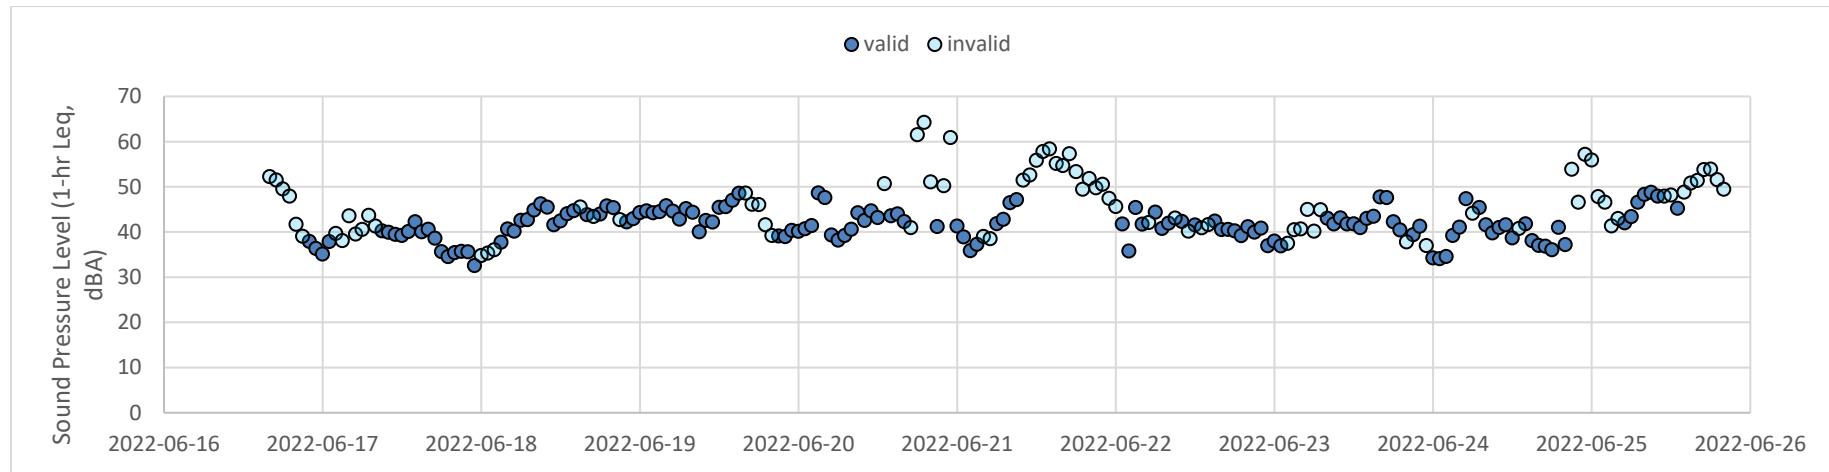

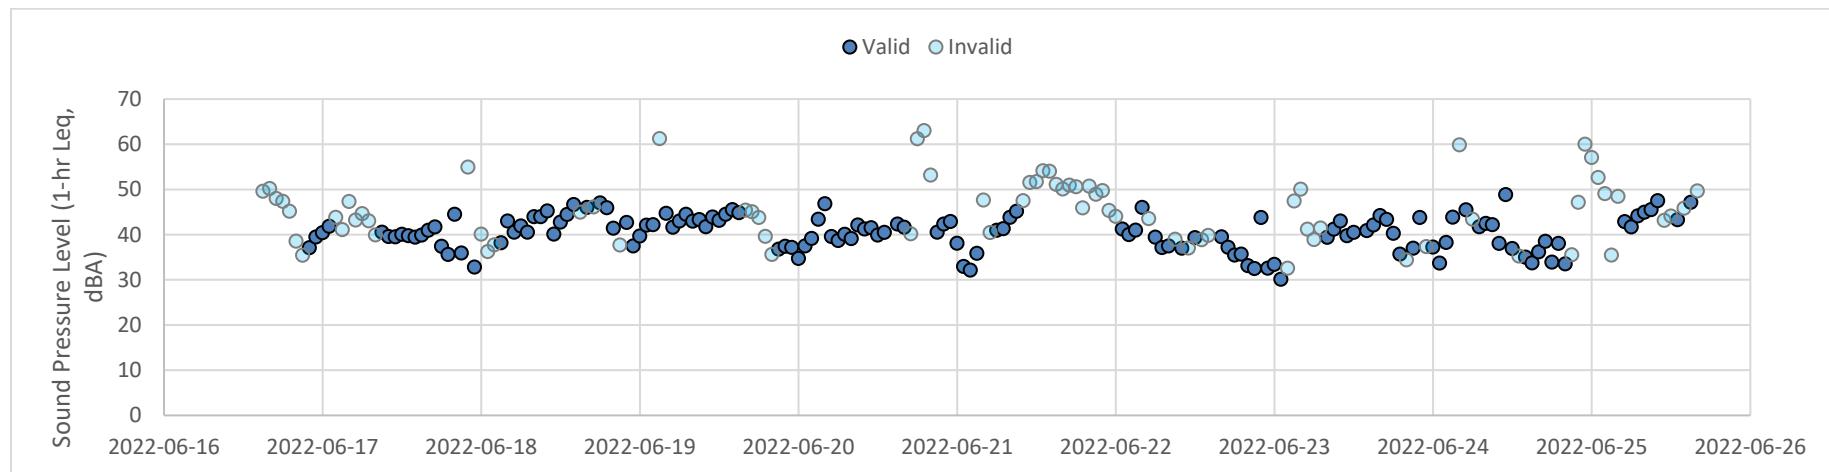

CAMPAGN #1

After the meteorological validation, it was found that nine (9) hourly sound levels exceeded the threshold of 50 dBA at NM-1, and six (6) at NM-2. The sound recordings collected as a result of the event trigger were reviewed to determine whether sound attributable to mine activity was occurring; however, it was found that the sounds were dominated either by bird calls occurring close to the meter, wind gusts, or onset of thunder prior to a rain event. The final results of the first monitoring campaign are summarized in Table 3.

A full summary of the hourly monitoring data is provided in Figure 2 and Figure 3, inclusive of the points that were invalidated for completeness of record (the invalid data points are identified using a different marker than the valid points). A corresponding data table is provided in Appendix A.

CAMPAIGN #2

After the meteorological data validation, it was found that there were six (6) hourly measurements out of 137 hours of valid data that exceeded the hourly Leq threshold of 50 dBA at NM-2. The sound recordings collected with the measurement data were used to identify what was occurring during the hours with exceedances. In each case, it was found that the sounds were dominated either by bird calls occurring close to the meter, wind gusts, or onset of thunder prior to a rain event. As such, these data points were removed from the data set. A summary of the final monitoring results from the second campaign are summarized in Table 4.

Figure 16: Noise Monitoring Summary at NM-2 (Campaign #2)

CONCLUSIONS

In accordance with the *Overall Benefits Permit* issued to the New Gold Rainy River Mine (Permit No. FF-C-001-14), noise monitoring of the Eastern Whip-poor-will habitat in the vicinity of the Rainy River Mine was completed in 2022. While the permit specifically identifies that the monitoring take place during the first week of May and in June, measurements were instead completed in June, in accordance with the permit, and another round was completed at the beginning of July. It should be noted that the Ontario MECP has identified that nesting season for the Eastern Whip-poor-will typically extends into July and sounds of the Eastern Whip-poor-will were recorded during the July program.

Activities being completed at the Rainy River Mine during the measurement campaigns included blasting, dam construction, crushing, loading, hauling, dumping, and rock placement. As per the Overall Benefits Permit, the noise monitoring is to indicate whether operations at the mine contribute to sound levels at the Eastern Whip-poor-will habitat at levels exceeding 50 dBA on a 1-hour basis (i.e., 1-hour Leq). The results of the measurements were first validated against concurrent meteorological measurement data, and then against sound recordings triggered by any exceedances of the 50 dBA threshold on an instantaneous basis. The resulting data sets for the June and July campaigns were each well in excess of the minimum of 48 hours of measurement data required by the MECP for continuous measurement programs.

A total of nine out of 141 hours were in excess of the 50 dBA threshold at the NM-1 location after the meteorological validation step during campaign #1 (the instrument did not log data in campaign #2). At NM-2, a total of seven hours out of the 276 hours of valid data (inclusive of both campaigns) were in excess of the 50 dBA threshold after the meteorological validation step. Sound recordings for each of these hours were reviewed to determine whether the operations at the Rainy River Mine were audible; however, in each instance the dominant sound was either bird calls which appeared to be sounding very close to the microphones, wind gusts, or presence of thunder prior to rain events. As such, these hours were removed from the data set as they were not representative of Rainy River Mine operations. This resulted in all other hourly sound levels remaining below the 50 dBA threshold.

Finder:

Information Provided For Event

Pelicans are often seen in and around clean water ponds at Rainy River mine, estimated population 20-30 birds in smaller flocks throughout the site. 2 were found dead on different water bodies on site, this one was found on the shore of a sediment pond where Pelicans are often seen roosting. One other carcass was found on the dam of a different water body but had been scavenged beyond use for testing. The third bird was found appeared to be sick and stuck on a tailings beach, it did not react to hazing methods. This bird was dispatched by firearm as tailings are unsafe to walk on.

Diagnosis and Interpretation

Final Diagnosis

1. SUSPECT HIGHLY PATHOGENIC (H5N1) AVIAN INFLUENZA

Interpretation

As this pelican was found dead and it had a positive test result for influenza virus, it is suspected that an infection with the highly pathogenic strain (H5N1) of avian influenza is responsible for the sudden death of this bird. As we have received many pelicans with similar clinical signs and test results, we will not be performing a post-mortem examination of this bird. If we receive results on the specific strain of the virus from the CFIA then an addendum will be added to this report with those results.

Although risk of transmission to humans is considered to be low, anyone who was in contact with this bird prior to its death should monitor for symptoms of avian influenza.

Additional information about this disease in people can be found on the Ontario Ministry of Health and Long-Term Care website.

General information: <https://www.health.gov.on.ca/en/pro/programs/emb/avian/default.aspx>

FAQ (including clinical symptoms to monitor for): <https://www.health.gov.on.ca/en/pro/programs/emb/avian/faq.aspx>

Additional resources: <https://www.health.gov.on.ca/en/pro/programs/emb/avian-links.aspx>

Laboratory Results

PCR

Oropharyngeal and cloacal swabs were **POSITIVE** for Influenza A virus by RT-PCR-Cycle threshold 32.87
Influenza A, H5 PCR
Result—**POSITIVE 30.46**

Influenza A, H7 PCR
Result—Negative

Cycle threshold (Ct) is the cycle number when signal increases above the background. Ct is inversely related to target concentration - lower Ct indicates higher concentration of target nucleic acids in the sample.
Ct 35.99 or less = POSITIVE
Ct 36.00 or higher = Inconclusive
Ct Not detected = Negative (the target was either not present or was below the detection limit).

Avian Influenza Virus

Test result: Positive

Pathologists Brian Stevens DVM, DVSc, DACVP.
