EXECUTIVE SUMMARY

The Rainy River Mine (RRM) is owned by New Gold Inc. (New Gold). The mine is located approximately 65 km northwest of Fort Frances and 420 km northwest of Thunder Bay, Ontario. The RRM is located within the Pinewood River watershed which flows past the mine, eventually draining into the Rainy River approximately 40 km downstream.

Operations at RRM presently include an open pit and underground mining with ore processed at the Rainy River Mill, located on site. The mine has an anticipated mine life of around 16 years (AMEC 2014). The mine came into commercial production in September 2017 and is currently subject to amended Environmental Compliance Approval (ECA) Number 7004-BC7KQ5 as issued by the Ontario Ministry of Environment, Climate and Parks (MECP). The Amended ECA includes an allowable throughput of up to 32,400 tonnes of ore per day with a quarterly average throughput of up to 27,000 tonnes per day.

The current Environmental Compliance Approval (ECA, #7004-BC7KQ5) issued on February 11, 2020 and the former ECA (# 5178-9TUPD9) contain(ed) a number of conditions to assess the potential effects of the mine, particularly discharge and flow regime change, on the receiver, the Pinewood River. This report has been prepared to meet:

- ECA #7004-BC7KQ5 Condition 9(3) and Condition 12(8) – A long-term study to evaluate the potential effects of flow reductions on the biological communities within the Pinewood River watershed;
- ECA #7004-BC7KQ5 Condition 10(10) and Condition 12(10) – Potential loadings of sulphate and mercury to the Pinewood River watershed; and,
- Paragraph 35(2)(b) Fisheries Act Authorization #15-HCAA-00039 Condition 2.2.4.

These three above requirements are to be assessed in accordance with the following Terms of Reference (TOR) submitted to MECP as well as in compliance with the terms and schedule within the New Gold Fisheries Offset Plan (AMEC 2015).

- Terms of Reference: Study to Assess Potential Mercury Loadings to the Pinewood River Watershed. Per Environmental Compliance Approval #5178-9TUPD9 Condition 8(5). Version 1, August 2016
- Pinewood River Biological Monitoring Plan. Per Environmental Compliance Approval #5781-9VJQ2J Condition 10(5) and #5178-9TUPD9 Condition 8(7). Version 2. December 2016.

Overview of the Pinewood River Annual Monitoring Study

The annual assessment of a potential mine-related impact on the Pinewood River includes an assessment of:

- water depth in both impounded and non-impounded habitat at four locations in the Pinewood River; (hereafter, Water Level Monitoring);.
- surface water quality including two reference and four possibly mine-influenced downstream locations (hereafter, Mercury and Sulphate Loadings Surface Water Assessment);
- the fish community (hereafter, Fish Community Survey); and,
- small-bodied fish mercury tissue concentrations (hereafter, Fish Tissue Analysis).

Conclusions

The current study provided the following conclusions:

- Water level loggers indicate that Area 1, 3, and 4 continue to exhibit seasonal and habitat type differences in water level fluctuations mirroring precipitation variations. Area 2 impoundment and non-impoundment water depths are higher than other Areas. There is no distinct pattern identified to suggest that impoundment and non-impounded areas are affected by mine-related activities. Beaver activity along the Pinewood River has contributed to the pooling of water along sections of the river and is a possible factor influencing water levels in this vicinity.
- In 2022, mining is likely not a major contributing factor to surface water concentrations of mercury in the Pinewood River. Total and dissolved mercury surface water concentrations across all sites and months were below detection limits and below both Ontario PWQO of 200 ng/L and CCME guidelines of 26 ng/L for dissolved mercury.
- In 2022, methylmercury concentrations at potential exposure sites continue to remain low and in most cases below the values observed at the reference locations. All concentrations were below CCME guidelines of 4 ng/L.
- Fish communities in the reference and exposure areas continue to be diverse with then (10) to 15 species being identified and with various age classes present. Density and dominant species varied between areas and between years.
- At all three sampling locations (Reference - PWREF, Near-field - PWNF, and Far -field - PWNF), Common Shiner (*Luxilus cornutus*) fish tissue mercury concentrations continue to remain below the consumption guideline value for sensitive populations (0.5 mg/kg, MECP 2015). PWREF and PWFF concentrations were below the working MECP SDB

guideline for the protection of fish-eating wildlife of 0.2 mg/kg and PWNF concentrations were at or near that guideline.

- Common Shiner fish tissue mercury concentrations were influenced by a combination of sample location, fork length and sample year. Despite being below the 0.5 mg/kg consumption guideline, PWNF has consistently higher mean tissue mercury concentrations than PWREF; its magnitude of difference (MOD) relative to PWREF is consistently above 25% based on multiple models (pairwise comparisons from a 2022-data ANOVA model and ANCOVA model and from a 2019–2022 ANCOVA model).

- The second species for tissue mercury concentration analysis, Central Mudminnow (*Umbra limi*), had nearly half the mean tissue mercury concentration of Common Shiner at the same sites but reflected and confirmed the same relative differences between PWNF and PWREF as Common Shiner.

Recommendations

The below are suggestions to modify or improve the program.

1) Assess the timing and frequency for the collection of surface water for mercury testing. total and dissolved mercury are typically less than their detection limits despite detections of methylmercury. A method with a lower detection should be investigated.

2) Continue to additionally sample Central Mudminnow for between-species comparisons across sites but increase the number of fish targeted to at least 10.

3) Further exploratory analysis of surface water constituent correlations and their correlations with fish tissue mercury concentrations may reveal drivers of differences between sites.

4) Investigate the feasibility of sampling sediment pore water for mercury constituents to develop a spatial model that describes site-and reach-scale variability in PWREF, PWNF, and PWFF sediments. Personal communications with RRM Environment Department Staff indicate the fragmented nature of sites from various causes such as beaver dams that may lead to fish affinity or movement restrictions based on natural barriers.

5) Continue to monitor and augment the study as necessary based on the mine established discharge practices.

LIST OF FIGURES

1.0 Introduction

1.1 Background Information

The Rainy River Mine (RRM) is a gold-silver mine located in northwestern Ontario in the District of Rainy River, approximately 65 km northwest of Fort Frances and 420 km west of Thunder Bay (**Figure 1-1**). Located within the Pinewood River watershed, the Pinewood River flows past the RRM and continues for approximately 40 km until the confluence with Rainy River. The mine occupies approximately 6,050 hectares of land and is owned by New Gold Inc. (New Gold).

The RRM began processing ore in September 2017, fifty years after it was first explored in 1967. In 2005, the project was acquired by Rainy River Resources Ltd. with initial baseline studies conducted in 2008. In 2013, the RRM was acquired by New Gold. An Environmental Assessment (EA) report, which included baseline conditions, was submitted in 2014 (AMEC 2014). Provincial and Federal EA approvals were granted in 2015 leading to the RRM site construction.

1.2 Objectives of the Current Report

Effluent discharge at the mine is intermittent and is regulated by the mine's current provincial ECA (Number 7004-BC7KQ5) issued by the MECP February 11, 2020. This ECA provides flow and seasonal requirements for discharge. Discharge of both treated water and site run-off is intermittent and based on precipitation rather than mine production with the mine being self-sufficient from a water recycling point of view. The location of the three discharge points is provided in **Figure 1-2**.

Compliance with New Gold's ECA conditions as well as conditions of their Fisheries Act Authorization #15-HCAA-00039 require several annual aquatic studies to be conducted on the Pinewood River. The study components described herein are intended to meet the requirements of Condition 9(3) and Condition 10(10) of the current ECA and were conducted following methods established in previously submitted Terms of Reference (AMEC, 2016, 2016b). Some of the biological effects components of the assessment of mine effluent discharge on the Pinewood River to satisfy Condition 10(9) have been harmonized with the timing of the Federal Environmental Effects (EEM) monitoring programs and are provided under separate cover (Ecometrix 2021a, b).

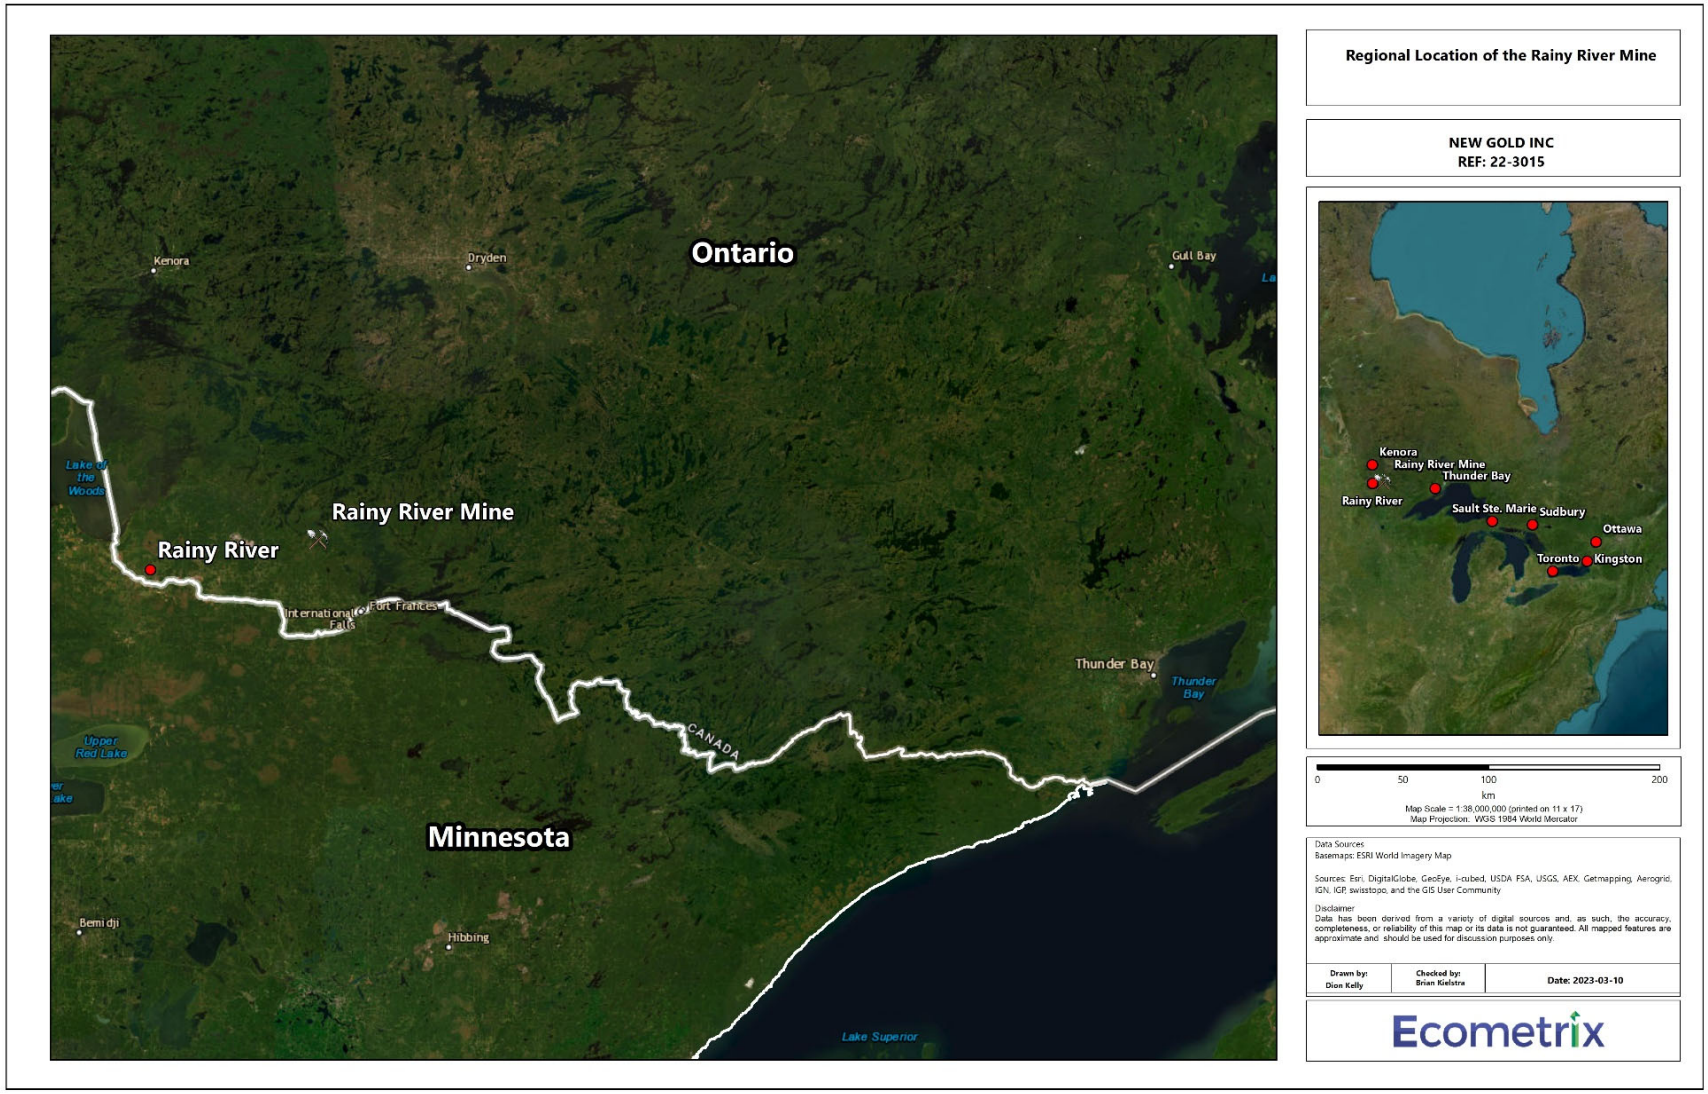

Figure 1-1: Regional location of the Rainy River Mine.

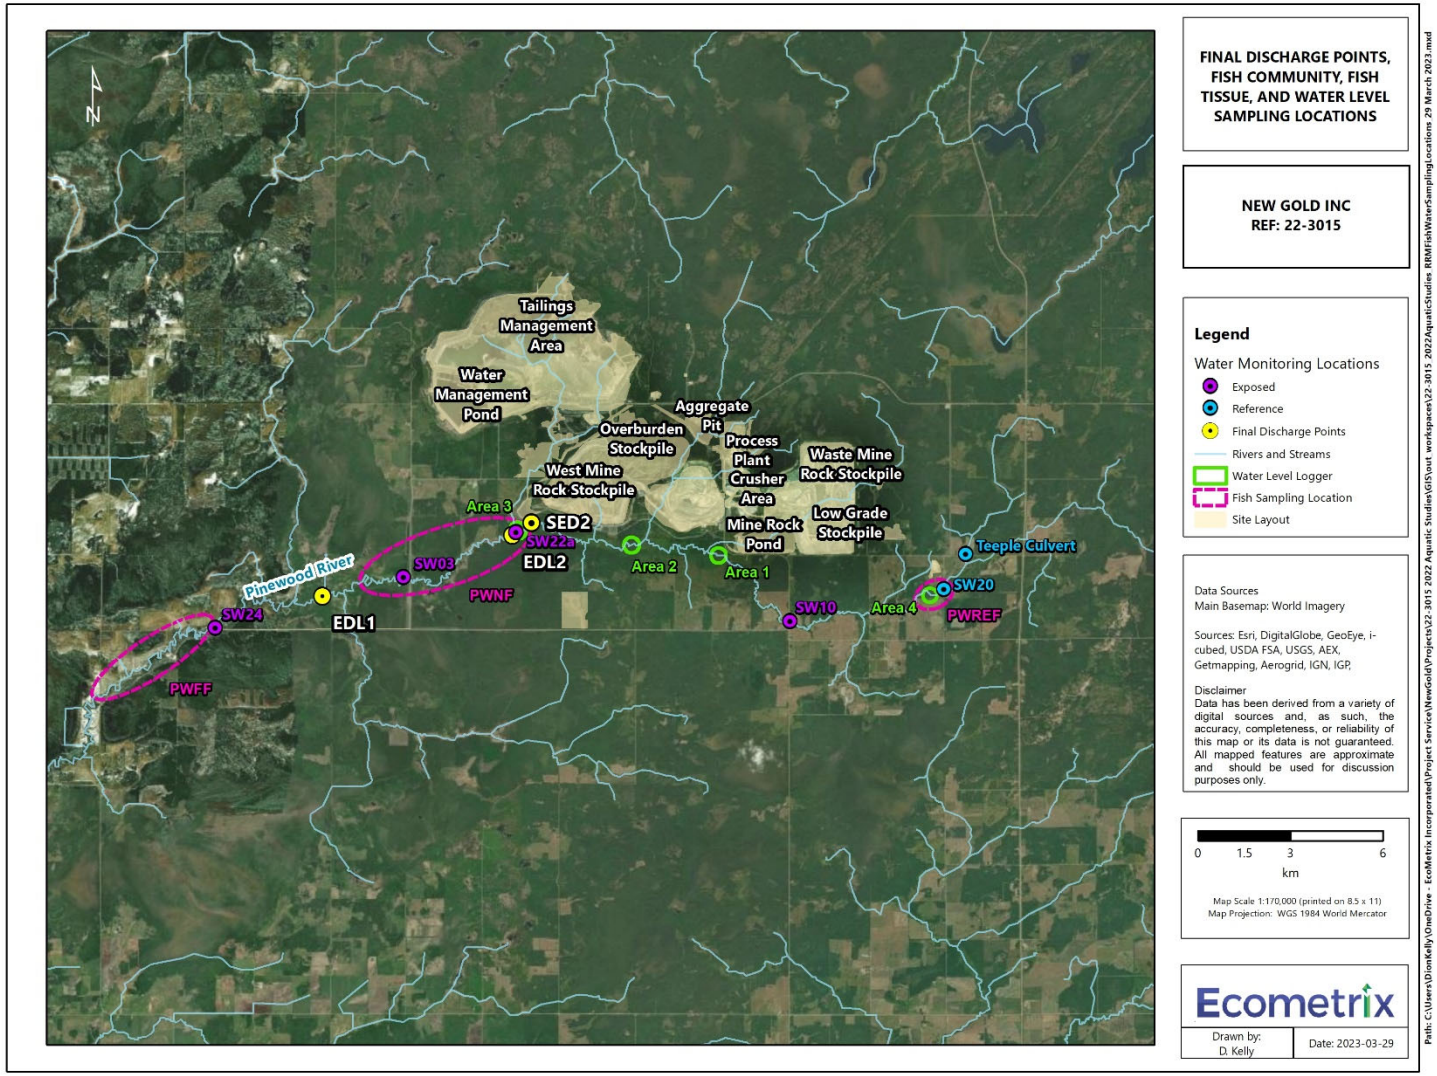

Figure 1-2: Water level monitoring, water quality monitoring, fish sampling locations, and other geographic reference points along the Pinewood River at Rainy River Mine.

2.0 General Approach to Pinewood River Annual Monitoring Program

The 2022 Pinewood Annual River Monitoring Program consisted of surveys aimed at evaluating potential effects associated with changes in flow of the Pinewood River and effluent discharge on the resident Pinewood River fish community. The four components were:

1. Water Level Monitoring;
2. Mercury and Sulphate Surface Water Assessment;
3. Fish Community Survey; and,
4. Fish Tissue Analysis.

The Water Level Monitoring and Mercury and Sulphate Surface Water Assessment components were completed from January to December 2022. To address changes to water level, two previously installed water level loggers were monitored in impoundment and non-impoundment locations within four areas along the Pinewood River (**Figure 1-2**). To address changes in Mercury and Sulphate concentrations, water samples were collected from four potential exposure stations and two upstream reference stations along the Pinewood River (**Figure 1-2**). Measurements were qualitatively compared across sites in 2022 and against the time series from previous reports.

The Fish Community Survey and Fish Tissue Analysis component sampling occurred over two field surveys, July 20 to July 28 and from August 31 to September 4, 2022, during the typical low water season as outlined in the Terms of Reference (TOR) (AMEC 2016). Three areas along the Pinewood River near the mine were sampled: two exposure areas downstream of each of the major effluent discharges, and one reference area, upstream of the mine site and outside the influence of the mine operations. These areas were the same as those used in previous iterations of the monitoring program:

- the Reference area (PWREF) upstream of RRM.
- a Near-field area (PWNF), downstream of the EDL2 Loslo Creek discharge; and,
- a Far-field area (PWFF), downstream of the EDL1 discharge (**Figure 1-2**).

The fish community assessment utilized, at the minimum, the prescribed amount of fishing effort required according to the TOR (AMEC, 2016b). The amount of minimum effort is provided in **Table 2-1**

Details of the individual components for the assessments are provided in subsequent sections.

Table 2-1: Summary of Annual Pinewood River Monitoring Program Components

Attribute	Monitoring Requirement	Report Schedule
Fish Habitat	Water Level monitoring (2 loggers per area; 1 for non-impounded [Type 1] habitat and 1 for impounded [Type 2] habitat).	Annual Reports are due to both the MECP and the DFO on or before March 31 of each year.
Fish Species Presence (Richness), Life Cycle Usage (Length frequency histograms), Abundance (Catch Per Unit Effort), and Tissue Quality (Mercury concentrations)	Fish Sampling will be conducted annually during the summer for 5 years.	
	Tissue quality sample size per area: 50 adult Common Shiner	
	Minimum effort per area: • Minnow traps (600 traps hours) • Seine nets (9 individual, 15 m net hauls • Electrofishing (3,000 seconds) • Gill nets (6 standard gill net sets (50 m multiple mesh panels for 12 to 16 hrs per set.	

3.0 Water Level Monitoring

The following section outlines work completed and results of the Water Level Monitoring component. The key results are as follows:

- Impoundment and Non-impoundment habitats continue to show seasonal variability in water levels. Area 3 exhibits the greatest fluctuation in water levels.
- July and August 2022 saw the highest precipitation recorded over the past 5 years. This resulted in an uncharacteristic rise in water levels in all Areas during this summer period.
- Water levels in Areas 1, 3 and 4 generally decreased after August 2022 with minor fluctuations. Area 2 impoundment and non-impoundment water levels however gradually increased, with water depths, higher than the other Areas.
- There is no distinct pattern identified to suggest that impoundment and non-impounded areas are affected by mine-related activities.

Further details are outlined in **Sections 3.1–3.3** below.

3.1 Sample Collection

In 2017, eight Solinst 3001 LT Levelogger Edge M10 water level loggers were installed to monitor water levels in the Pinewood River. Pairs of loggers were installed in four areas with one logger installed in a narrow non-impounded area (Type 1 Habitat) and the other installed in an impounded area (Type 2 Habitat; AMEC 2018a). Loggers recorded water depth and temperature at 15-minute intervals. Loggers were retrieved and data were downloaded and provided to Ecometrix by the RRM Environment Department.

Data for Area 4 Type 1 Habitat were not available in 2022 due to site access issues

3.2 Data Analysis

Ecometrix exported raw data from logger download files using Solinst Levelogger Software. Data were screened for abnormal values. Levelogger sensor values were barometrically corrected and converted to units of pressure in metres of water (mH2O).

3.3 Results

Plots of non-impounded Type 1 Habitat reflected annual cycles and seasonal changes related to precipitation. January to March showed marginal decreases in water levels across all non-impoundment habitats. As precipitation gradually increased in April and May (monthly average precipitation of 4.6 mm and 4.2 mm respectively) there were substantial increases in the water levels; Area 1 peaked at approximately 1.9 m, Area 2 at approximately 2 m, and Area 3 at approximately 3 m (**Figure 3-1**). This followed the yearly trends with water level increases coinciding with spring freshet and Area 3 again showing the largest fluctuations in water level.

There was a decline in water levels across Areas 1 and 3 until July where an uncharacteristic increase in precipitation again contributed to increases in water levels; peaking at approximately 1.6 m and approximately 2.4 m for Areas 1 and 3 respectively. The last quarter of the year saw both Areas 1 and 3 having water levels between 1 and 1.5 m.

The latter half of the year saw water levels at the non-impoundment Area 2 generally increase and remain between 1.6 and 1.8m (**Figure 3-1 Table 3-1**). The relatively marginal fluctuations in water levels at Area 2 were also observed in previous years (Minnow, 2021). Beaver activity along the Pinewood River has contributed to the pooling of water along sections of the river and is possible a factor influencing water levels in this vicinity.

July and August in 2022 had the highest precipitation recorded in the last 5 years. No distinct pattern was identified to suggest the non-impounded areas are affected by mine-related activities.

The water levels within impoundment habitat mirrored the variability seen in the non-impoundment areas, fluctuating with seasonal patterns, and changes in precipitation. These areas were relatively shallower than the non- impoundment areas. Water levels were generally low in the first quarter of the year before increasing during the spring freshet; Area 1 peaked at approximately 1.8 m, Area 2 at approximately 2.6 m, Area 3 at approximately 2.5 m and Area 4 peaked at approximately 1.6 m during May 2022 (**Figure 3-1**). Water levels then decreased before rising again with the increased rainfall during July (Area 1 peaked at approximately 1.5 m, Area 2 at approximately 2.3 m, Area 3 at approximately 1.9 m, and Area 4 at approximately 1.8 m (**Figure 3-1**). The remainder of the year saw water levels in Areas 1, 3, and 4 averaging between 0.5 and 1 m. Water levels in Area 2 however averaged between 2.0 and 2.4 m.

Overall, the water level response in 2022 was similar to previous yearly increases during spring freshet and the 5 year high increased precipitation during June through August 2022. Area 3 continues to show the greatest fluctuation in water levels amongst both impoundment and non-impoundment areas, typically having lower flows during September to March than the other areas, and conversely having higher peak flows during April through June (**Figure 3-1**). Water depth patterns in the impounded areas do not indicate mine-related impacts on the flow regime in the Pinewood River.

Table 3-1: Water levelogger summary statistics by Habitat type and Area in 2022.

Habitat	Area	Mean	SD	CV	Min	Q25	Q50	Q75	Q95	Max
1 – Non-impounded	1	1.363	0.140	0.103	1.119	1.265	1.330	1.416	1.661	1.901
	2	1.625	0.159	0.098	1.291	1.487	1.657	1.765	1.818	2.117
	3	1.250	0.408	0.327	0.661	0.898	1.236	1.415	2.067	3.008
2- Impounded	1	1.040	0.164	0.157	0.842	0.933	0.980	1.092	1.395	1.801
	2	2.267	0.158	0.070	1.942	2.126	2.295	2.415	2.471	2.615
	3	0.772	0.413	0.534	0.200	0.420	0.742	0.945	1.608	2.551
	4	1.002	0.152	0.152	0.743	0.876	0.968	1.121	1.265	1.617

Note: SD is standard deviation, CV is coefficient of variation, Q represent quantiles (i.e., percentiles) Units except for CV in mH2O

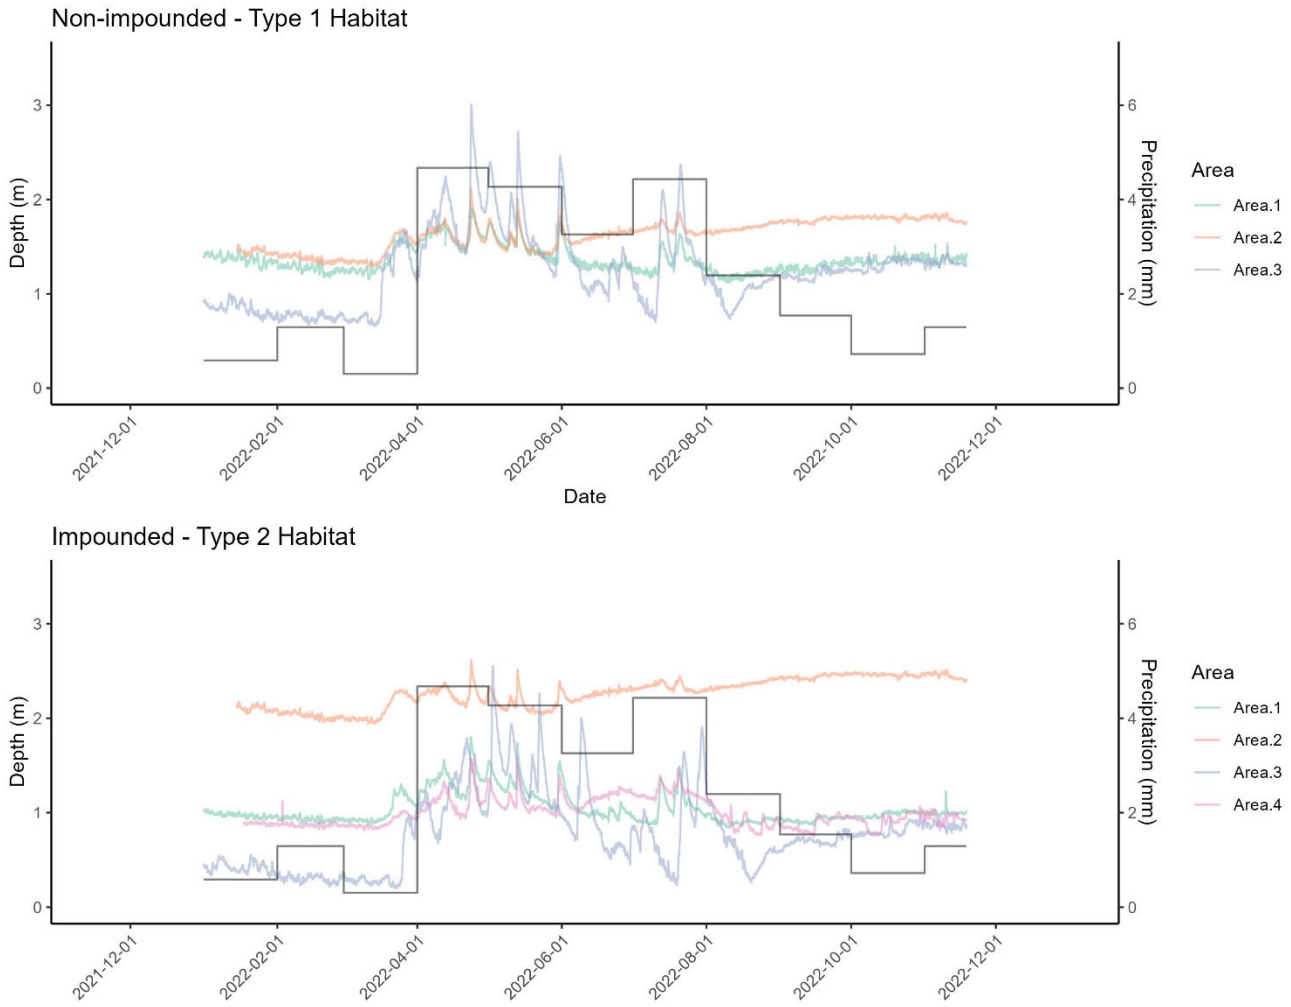

Figure 3-1: Water level logger data from the Pinewood River in Non-impounded Type 1 and Impounded Type 2 habitat types in 2022. Areas in Figure 1-2.

4.0 Mercury and Sulphate Surface Water Assessment

The following section outlines work completed and results of the Mercury and Sulphate Surface Water Assessment component. The key results are as follows:

- In 2022, total and dissolved mercury surface water concentrations across all sites and months were below detection limits and below both Provincial Water Quality Objectives for Ontario (PWQO) of 200 ng/L and CCME guidelines of 26 ng/L dissolved mercury;
- In 2022, methylmercury surface water concentrations were above detection limits, reference sites had, on average, higher concentrations than exposure sites, and all concentrations were below CCME guidelines of 4 ng/L; and,
- In 2022, total sulphate concentrations were all below the 309 mg/L total sulphate BCMECCS guideline at 148 mg/L hardness and generally below the most conservative guideline of 128 mg/L total sulphate used for 0 mg/L hardness.

Further details are outlined in **Sections 4.1–4.3** below.

4.1 Sample Collection

RRM Environmental Department staff collected the routine water quality samples for the Mercury and Sulphate Surface Water Assessment component as part of their monthly sampling requirements during the open water season. Samples were collected at two reference locations upstream of the mine (Teeple Culvert and SW20) and four stations proceeding downstream from potential mine influence along the Pinewood River (SW10, SW22A, SW03 and SW24). Sample locations in relation to the mine infrastructure are provided in **Figure 1-2** and are the same as those used in previous annual assessments.

Each sample was collected below the surface into an upstream facing pre-labelled sample bottle to avoid floating material and contamination by the sample collector. Preservative was added in the field following collection, if required. Samples were kept in coolers with ice and transported to the RRM environmental laboratory. Upon arrival at the laboratory on site samples were either shipped the same day or stored in the refrigerator prior to shipment to ALS in Thunder Bay. Each sample was analyzed for mercury (total, dissolved, and total methylmercury) and total sulphate.

4.2 Data Analysis

Each of the four water quality parameters (total mercury, dissolved mercury, methylmercury, and total sulphate) were evaluated graphically both within the 2022 sampling year and by comparing the mean values at each sampling locations for each parameter since the program began in 2017.

Concentrations reported were also compared to both PWQO (OMOEE, 1994) and the more recent BC Ministry of Environment & Climate Change Strategy water quality guidelines (BCMECCS 2019, 2021).

Following AMEC (2016), two-way Analysis of Variance (ANOVA) was undertaken to examine differences in means between reference (Teeple Culvert and SW20) and exposure (SW10, SW22A, SW03, and SW24) and across months. Only methylmercury and total sulphate models were completed because all values for total mercury and dissolved mercury were below detection limits (DL).

4.3 Results

Based on the surface water quality data, there is no indication mine-related increases in any mercury constituents in the Pinewood River in 2022.

In 2022, surface water concentrations of total and dissolved mercury at all sites were below detection limits of 5 ng/L and therefore below the Ontario PWQO of 200 ng/L and CCME guideline of 26 ng/L (**Figure 4-1**). Across years, mean concentrations are relatively stable (at or near detection limits and below guidelines) and any large changes in mean concentrations (e.g., 2020) appear to be driven by DL changes rather than site conditions (e.g., in 2020, many reported DL were 30 ng/L) (**Figure 4-2**).

In 2022, nearly all samples had detectable concentrations of methylmercury (DL = 0.02 ng/L) although all were below the CCME guideline of 4 ng/L (**Figure 4-1**). There were significant effects of Area (reference vs. exposure; F =29.9, p < 0.001) and Month (F = 6.6, p = 0.003) but no interactive effects based on the two-way ANOVA. Estimated mean reference concentration averaged over all months were 0.74 (0.58–0.89 95% CI) ng/L whereas mean exposure concentration was 0.37 (0.27–0.51 95% CI) ng/L. Exposure concentrations were estimated to be 48% lower than reference, on average. Across years, mean concentrations were also relatively stable (similar mean concentrations ± 1 SD) with mean concentrations below the CCME guidelines of 4 ng/L (**Figure 4-2**).

In 2022, all samples had detectable concentrations of total sulphate, but all samples were below the lowest conservative BCMECCS guideline of 128 mg/L total sulphate used for 0 mg/L hardness. For comparison, the guideline at 148 mg/L hardness is 309 mg/L total sulphate (mean hardness concentration across all samples for reference sites) (**Figure 4-1**). There was a significant main effect of Month (F = 2.25, p = 0.03) but not Area (p > 0.05) or their interaction (p > 0.05). The November sample was identified as having higher concentrations which was driven by two high measurements at SW03 and SW24 on November 12, 2022 (**Figure 4-1**). Apart from these instances, total sulphate concentrations in reference and exposure sites were, on average, lower than the previous two years with mean concentrations lower than the applicable guidelines and standards (**Figure 4-2**).

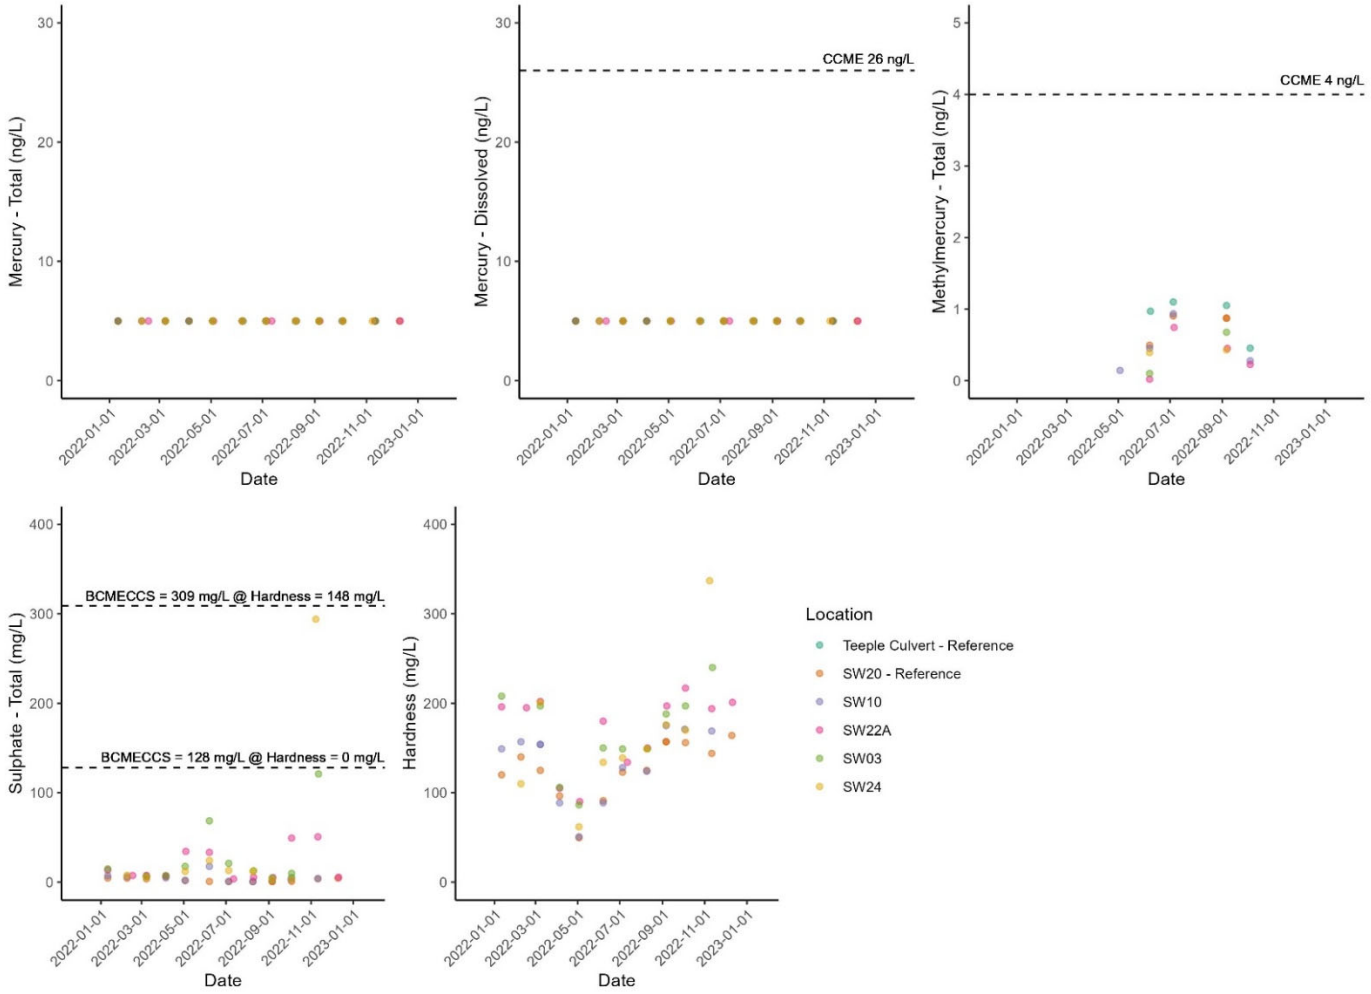

Figure 4-1: Water sample concentrations of Total Mercury, Dissolved Mercury, Methylmercury, Sulphate, and Hardness at surface water sampling locations, 2022

Note: CCME and BCMECCS guidelines presented for reference; the BCMECCS guideline for Sulphate is the most conservative level (Hardness = 0 mg/L). The Ontario PWQO for Dissolved Mercury is 200 ng/L. Locations are ordered from most upstream to most downstream.

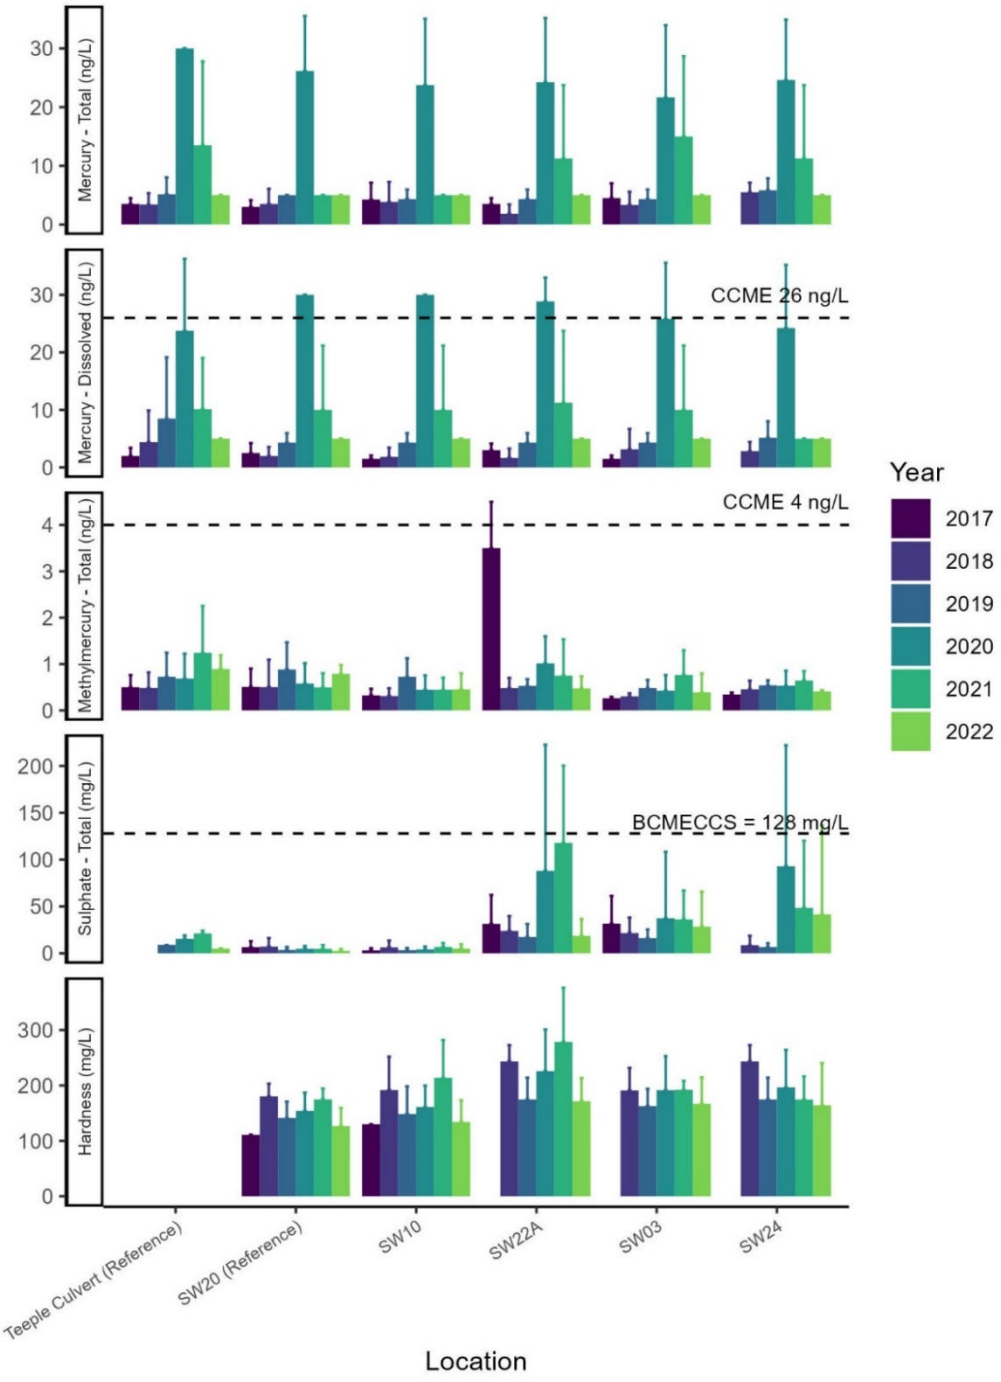

Figure 4-2: Mean water sample concentrations (error bars: + 1 Standard Deviation) Total Mercury, Dissolved Mercury, Methylmercury, Sulphate, and Hardness at surface water sampling locations, 2017 to 2022.

Note: CCME and BCMECCS guidelines presented for reference. Locations are ordered from most upstream to most downstream**.**

5.0 Fish Community Survey

The following section outlines work completed and results of the Fish Community Survey component. The key results are as follows:

- PWREF, PWNF, and PWFF had similar species compositions and species richness in 2022. PWREF had 13 species, PWNF had 10 species, and PWFF had 15 species not including the general category of Young-of-the-Year (YOY).
- Despite fish abundance being lower within PWNF and PWFF in 2022, this trend has been apparent since 2017. The relative difference to PWREF remains similar to previous years and through time.
- Length frequency histograms indicate that multiple age classes of a variety of species were captured in 2022 across all areas.

Further details are outlined in **Sections 5.1**–**5.3** below.

5.1 Sample Collection

The fish communities at Pinewood River reference (PWREF), near-field (PWNF), and far-field (PWFF) areas were surveyed utilizing a backpack electrofisher unit, seine nets, overnight minnow trap effort and gill net sets. The backpack electrofishing unit was adjusted to appropriate voltage, frequency, and duty cycle settings based on target fish size, water conductivity, and temperature to minimize the risk of harm to fish. Seine nets, with a minimum area of 15 m^2, were hauled in each study area. At least nine seine nets were cast in each area. Minnow traps were baited with dry dog food prior to deployment and checked every 24 hours.

All fish captured were identified and enumerated. Live non-sentinel and excess sentinel species fish were released back into the area from which they were collected. Incidental mortalities were recorded and disposed of as per the conditions of the Licence to Collect Fish for Scientific Purposes No. 1098775 issued by the Ontario Ministry of Natural Resources and Forestry.

Adult Common Shiner and Central Mudminnow were retained for further processing.

5.2 Data Analysis

Following AMEC (2016), the catch per unit effort (CPUE) for each fishing method (electrofishing, gill netting, seine netting, and minnow trapping) were calculated per area. Species richness (number of individual species) per area were calculated to determine if species presence is maintained in each area. Length frequency distributions per species per area were graphed with the understanding that qualitative comparisons of results will show any large discrepancies in year classes.

5.3 Results

The fish community in PWREF included (listed in order of abundance) Pearl Dace (*Margariscus margarita*), Brook Stickleback (*Culaea inconstans*), Central Mudminnow, Common Shiner, Northern Redbelly Dace (*Chrosomus eos*), White Sucker (*Catostomus commersonii*) Creek Chub (*Semotilus atromaculatus*), Fathead Minnow (*Pimephales promelas*), Finescale Dace (*Chrosomus neogaeus*), Golden Shiner (*Notemigonus crysoleucas*), Northern Pike (*Esox lucius*), and Brassy Minnow (*Hybognathus hankinsoni*) (**Table 5-1**). Thirteen species were identified among the 1,175 individual fish captured (**Table 5-1**). The CPUE was 1.25 fish per hour of gill netting effort, 4.24 fish per 60 seconds of electrofishing effort, 74 fish per seine netting effort, and 0.15 fish per minnow trap hour (**Table 5-2** to **Table 5-5**). Length frequency histograms indicate that multiple age classes of a variety of species were captured in 2022 (**Figure A-1**).

The fish community identified in PWNF included (listed in order of abundance) Brown Bullhead (*Ameirurus nebulosus*), Common Shiner, Central Mudminnow, Northern Pike, White Sucker, Golden Shiner, Pearl Dace, Creek Chub, Brook Stickleback, and Fathead Minnow. There were 10 species identified among the 536 fish caught (**Table 5-1**). The CPUE for the various effort types were 0.17 fish per gill net hours, 0.49 fish per 60 seconds of electrofishing effort. 15.18 fish per seine netting effort, and 0.11 fish per minnow trap effort (**Table 5-2** to **Table 5-5**). Length frequency histograms indicate that multiple age classes of all species, including young of year fish for multiple species were captured in 2022 (**Figure A-2**)**.**

The fish community in PWFF included (listed in order of abundance) Common Shiner, Blackside Darter (*Percina maculata*), Central Mudminnow, Brown Bullhead, Brook Stickleback, Northern Pike, Rock Bass (*Ambloplites rupestris*), Creek Chub, Johnny Darter (*Etheostoma nigrum*), White Sucker, Fathead Minnow, Trout Perch (*Percopsis omiscomaycus*), Pearl Dace, Golden Shiner, and Walleye (*Sander vitreus*). There were 15 species identified among the 196 fish caught (**Table 5-1**). The CPUE at this site included 0.08 fish per gill net setting, 0.27 fish per 60 seconds electrofishing, 12.27 fish per seine net hauls, and 0.02 fish per minnow trap hours (**Table 5-2** to **Table 5-5**). Length frequency histograms indicate that multiple age classes of a variety of species were captured in 2022 (**Figure A-3**).

A total of 1,907 fish representing at least 15 species were captured during the 2022 Pinewood River fish community survey within the three areas (PWREF, PWNF, PWFF) (**Table 5-1**). Fish abundance has been lower within the PWNF and PWFF areas in all years since 2017. With the exception of changes in fish abundance, the fish community has been similar in all years from 2017 to 2021 indicating Rainy River Mine operations have minimal impact on the resident fish communities within the Pinewood River.

Table 5-1: Total catch by species in the Pinewood River, 2022

Species	PWREF	PWNF	PWFF
Blackside Darter	0	0	8
Brassy Minnow	3	0	0
Brook Stickleback	211	1	5
Brown Bullhead	29	212	6
Central Mudminnow	86	50	6
Common Shiner	74	162	63
Creek Chub	21	2	3
Fathead Minnow	16	1	2
Finescale Dace	10	0	0
Golden Shiner	9	7	1
Johnny Darter	0	0	3
Northern Pike	5	11	5
Northern Redbelly Dace	64	0	0
Pearl Dace	282	2	1
Rock Bass	0	0	5
Trout Perch	0	0	2
Walleye	0	0	1

6.0 Fish Tissue Analysis

The following section outlines work completed and results of the Fish Tissue Analysis component. Common Shiner was the primary target species for the analysis like previous reports. Common Shiner is typically found in the three study areas in sufficient density. Per the 2021 report recommendations, a secondary target of Central Mudminnow was used to assess bioaccumulation potential against Common Shiner for examining species-specific life history/niche bias associated with sampling a single species.

For reference, the MECP Standards Development Branch (SDB) working guideline for the protection of fish-eating wildlife is 0.2 mg/kg wet weight (wwt). Health Canada has also established a standard of 0.5 mg/kg wwt as the maximum acceptable concentration of mercury in commercially sold fish, enforceable by the Canadian Food Inspection Agency (Health Canada, 2007). Although this guideline is only applicable to commercially sold fish, 0.5 mg/kg wwt is also the level at which the MECP recommends a complete consumption restriction for vulnerable populations (i.e., women of child-bearing age and children under 15; MECP 2015). Common Shiner are not typically consumed by humans, yet this guideline is referenced to provide some perspective on mercury body burden levels in edible fish.

The key results are as follows:

- In 2022, Common Shiner mean tissue mercury concentrations at all sites were below the consumption guidelines for sensitive populations of 0.5 mg/kg. PWREF and PWFF concentrations were below the working MECP SDB guideline for the protection of fish-eating wildlife of 0.2 mg/kg and PWNF concentrations were at or near that guideline.
- PWNF has consistently higher mean tissue mercury concentrations than PWREF; its Magnitude of Difference (MOD) relative to PWREF is consistently above 25% and has increased through time based on multiple lines of evidence (pairwise comparisons from a 2022-data ANOVA model and ANCOVA model and from a 2019–2022 ANCOVA model)
- Central Mudminnow had nearly half the mean tissue mercury concentration of Common Shiner at the same sites but reflected the same relative differences between PWNF and PWREF as Common Shiner.
- Further exploratory analysis of surface water constituent correlations and their correlations with fish tissue mercury concentrations may reveal drivers of differences between sites.

Further details are outlined in **Sections 6.1**–**6.3** below.

6.1 Sample Collection

During the fish community assessment up to 50 adult Common Shiner and five Central Mudminnow were targeted for tissue metals analysis per area. All retained fish were measured

for both fork and total length to the nearest millimetre using a fish measuring board. Weight was determined (to the nearest milligram) using an appropriately calibrated analytical balance.

The collected fish were processed. Each fish head containing the otoliths was placed in a labelled Whirl-Pak™ bag. These were collected for the purposes of age determination. The remainder of the body was placed in an appropriately, labeled Whirl-Pak™ bag for the purposes of tissue chemistry analysis. Both samples were kept frozen.

At the conclusion of the field collections tissue samples were submitted to Bureau Veritas (BV) in, a laboratory that specialized in tissue analysis along with a chain-of-custody (COC) record. Total mercury and moisture analyses were conducted on a homogenized portion of each fish. The mercury concentrations were provided in wet weight values using the Cold Vapor Atomic Fluorescence methodology. Otoliths, along with a COC were shipped to AAE Tech Services Inc. in La Salle, Manitoba for fish age determination.

6.2 Data Analysis

Following AMEC (2016), two-way ANOVA was first used to investigate the main effects of Area and Age and their interaction on tissue mercury concentrations. A statistically significant interaction ($p<0.1$) would indicate Area differences are dependent on Age. No significant interaction was found so mean tissue concentration estimates were generated for PWREF, PWNF, and PWFF using a no-interaction model. The magnitude of difference (MOD) between areas was calculated using these estimates. It was calculated as:

$$MOD = (Exposure - Reference)/Reference \times 100,$$

where PWNF and PWFF were substituted as *Exposure* depending on the model and PWREF was *Reference*, respectively. Differences in tissue mercury concentrations between areas was considered not to be significantly different if MODs were lower than the critical effect size (CES) of 25%. If a MOD value was larger than the CES, mercury tissue concentrations were considered to differ significantly. This is analogous to CES found in MDMER technical guidance for other sublethal effects (EC, 2012).

A log-linear relationship is well established in the literature, where mercury tends to increase with body size (Tang et al., 2013). Statistical comparisons of mercury concentrations at common fish size (i.e., Fork Length) were examined between PWREF, PWNF, and PWFF like the 2021 report (Ecometrix, 2021a). This was achieved using Analysis of Covariance (ANCOVA) with log10-transformed wet weight tissue mercury concentrations as the response variable, Area as a factor variable (i.e., PWREF, PWNF, and PWFF), log10-transformed Fork Length as a covariate, and their interaction. MODs were calculated as above but at the minimum and maximum Fork Length values common across sites.

The linear relationships in the above ANCOVA analysis were compared with those in the 2021 report. The relationships varied between sites within the same year and varied between years within the same site. For example, the mercury-length relationship in PWREF was positive in

2021 but negative in 2022. These varied and potentially juxtaposed relationships make between-year interpretation difficult.

Therefore, a two-way ANCOVA of Area, Year, the Fork Length covariate, and their interactions was used to facilitate comparisons between sites within and across years using 2019–2021 data. Tissue mercury concentration estimates were generated for each Area:Year combination for a 6 cm Fork Length fish (the average minimum size across all sites and years), an 8 cm Fork Length fish (the average size across all sites and years), and a 12 cm Fork Length fish (the average maximum size across all sites and years). MODs were calculated using these estimates. Together, these pairwise comparisons provide a reasonable accounting of the last four years for identifying trends while the number of pairwise comparisons are relatively small; this analysis approach is in the spirit of the Before-After-Control-Impact and Generalized Additive Model analysis approaches identified in AMEC (2016).

Finally, an exploratory analysis was undertaken to examine correlations between fish tissue mercury concentrations and surface water chemistry. This was done using 2020–2021 data since tissue mercury concentrations in 2019 were generally outside of the range of the baseline (2012) and 2020–2021 data (**Figure 6-3**). Surface water stations were chosen as those immediately above PWREF, PWNF, and PWFF; these were SW20 (PWREF), SW22a (PWNF), and SW24 (PWFF). Surface water constituents were chosen to be representative of potential nutrient and mercury loading (**Table 6-4**). A Principal Component Analysis (PCA) was used to further examine constituent relationships across the study areas; PCA reduces many variables to newly derived variables that summarize the original information and allow for the investigation of patterns that might not be found by analyzing each variable separately (Quinn & Keough, 2002). Since PCA requires a complete *site* x *variable* matrix and since not all parameters were measured at each monitoring location, an optimal subset was found balancing the need for more sites and more parameters (**Table 6-4**). The final surface water constituents and PCA scores were aggregated to mean values per Area:Year combination (3 years x 3 areas) and correlated with their respective Area:Year mean Common Shiner tissue mercury concentrations using Spearman Rank Correlation tests.

For Central Mudminnow, the Total Length of fish was not sufficiently distributed within or between sites for an ANCOVA. There were also not sufficient Central Mudminnows caught in PWFF (n = 2; target was five). Instead, a subset of Common Shiners that fit within the minimum and maximum Total Lengths were compared to Central Mudminnow using ANOVA. A model that evaluated the main effects of species, area, and their interaction was run. If there was an interaction at $p < 0.1$, the concentration differed by species and that difference was dependent on the area. If there was no interaction but a significant effect of Species, then concentration differed by Species. If there was no interaction but a significant effect of Area, then the concentration was Area dependent.

6.3 Results

In 2022, Common Shiner mean tissue mercury concentrations at all sites were below the consumption guidelines for sensitive populations of 0.5 mg/kg (MECP 2015). PWREF and PWFF

concentrations were below the working MECP SDB guideline for the protection of fish-eating wildlife of 0.2 mg/kg and PWNF concentrations were at or near that guideline (**Table 6-1**).

When comparing areas in 2022 using ANOVA and ANCOVA, PWNF had consistently higher mean concentrations than PWREF with MODs greater than the 25% CES level suggested earlier. PWNF concentrations were 98% higher than PWREF based on the ANOVA model estimates, and 45% higher in smaller fish (6.4 cm) and 183% higher in larger fish (10.1 cm) based on the ANCOVA model estimates. PWFF MODs were more variable – concentrations were 25% higher than PWREF based on ANOVA model estimates, and 9% lower for smaller fish and 44% higher for larger fish based on ANCOVA model estimates (**Table 6-2**, **Figure 6-1** and **Figure 6-2**).

For the 2022 ANCOVA model, there was a significant Area by Fork Length interaction indicating that the log-linear relationship of tissue mercury concentration with Fork Length varied between sites ($F = 7.3$, $p < 0.001$) (

Table 6-2, **Figure 6-2**). The relationships also varied across years. For example, the mercury-length relationship in PWREF was positive in 2021 but negative in 2022 (Ecometrix, 2021a).

To better understand general patterns across sites and through time, the 2019–2022 ANCOVA model was used to generate mean concentration estimates for Area:Year combinations for 6 cm, 8 cm, and 12 cm Fork Length for calculating MODs. The model had significant Fork Length by Year ($F = 50.24$, $p < 0.0001$), Fork Length by Area ($F = 5.15$, $p = 0.006$), and Year by Area interactions ($F = 18.73$, $p < 0.001$) again confirming the variability in log-linear relationships by Year and Area and that Area differences are also dependant on Year. On average (2020-2022), PWNF was 120% greater than PWREF (range: 32–212%) for 6 cm fish, 78% greater for 8 cm fish (range: 34–101%), 79% greater for 12 cm fish (range: -31–264%). PWFF was 71% greater for 6 cm fish (range: -14–224%), 23% greater for 8 cm fish (range: -24–80) and 1% smaller (range: -31–264%). The PWNF is the most consistent relationship and is greater than PWREF for nearly all fish sizes and years; the MOD has also increased through time (

Table 6-3**, Figure 6-3**).

To better understand observed tissue concentrations as they relate to surface water concentrations, PCA was used as an exploratory tool to examine general patterns amongst surface water constituents. The first Principal Component explained 33% of the variation in chemistry and was most positively correlated with nitrate, nitrite, sulphate and total dissolved solids; samples with higher values of these constituents have more positive PC1 values. The second Principal Component explained 19% of the variation in chemistry and was most positively correlated with total and dissolved phosphorus. Surface water near PWREF (SW20) generally occupied a narrower range of conditions than PWNF and PWFF as indicated by the 95% confidence ellipse about the sites. This narrower range tended to have average values along PC1 and lower values along PC2 (i.e., lower nutrient concentrations). Surface water constituents were summarized to their mean values for Area:Year combinations and compared against Area:Year mean tissue mercury concentrations using Spearman Rank Correlations. Only dissolved phosphorus and dissolved organic carbon were correlated with tissue mercury

concentrations ($p < 0.1$). More explicit study of these relationships coupled with pore water sampling could reveal nutrient-mercury relationships at local or entire-reach scales.

For the comparison of Central Mudminnow with Common Shiner, five PWREF and four PWNF Central Mudminnow were compared against 37 PWREF and 43 PWNF Common Shiner, respectively. All fish had had lengths between 2.4 cm and 10.3 cm. The ANOVA results should be interpreted with caution because of the small Central Mudminnow sample size. There was a no interaction suggestive of Area-specific changes in the relationship between Common Shiner and Central Mudminnow. ($F = 1.41$, $p = 0.24$) However, this was a much smaller effect than the individual effects of area and species. Across species, the PWREF had nearly half the concentration of mercury than PWNF ($F = 34.17$, $p < 0.001$). Across areas, Central Mudminnow had nearly half the concentration of mercury ($F = 97.10$, $p < 0.001$) than Common Shiner. Across sites, given that fish are exposed to the same water, this difference may be explained by habitat exploitation or feeding. Both species are insectivores but Central Mudminnow tend to exploit benthic habitats whereas Common Shiner tend to exploit pelagic habitats (Eakins, 2023).

Table 6-1: Summary of Tissue Mercury Concentrations, Body Weight, Fork Length, and Ages of Common Shiners in the Upper Pinewood River during 2019, 2020, 2021, and 2022.

7.0 Conclusions and Recommendations

7.1 Conclusions

The current study provided the following conclusions:

- Water level loggers indicate that Area 1, 3, and 4 continue to exhibit seasonal and habitat type differences in water level fluctuations mirroring precipitation variations. Area 2 impoundment and non-impoundment water depths are higher than other Areas. There is no distinct pattern was identified to suggest that impoundment and non-impounded areas are affected by mine-related activities.

- In 2022, mining is likely not a major contributing factor to surface water concentrations of mercury in the Pinewood River. Total and dissolved mercury surface water concentrations across all sites and months were below detection limits and below both Ontario PWQO of 200 ng/L and CCME guidelines of 26 ng/L dissolved mercury.

- In 2022, methylmercury concentrations at potential exposure sites continue to remain low and in most cases below the values observed at the reference locations. All concentrations were below CCME guidelines of 4 ng/L.

- Fish communities in the reference and exposure areas continue to be diverse with 10 to 15 species being identified and with various age classes present. Density and dominant species varied between areas and between years.

- At all three sampling locations (Reference - PWREF, Near-field - PWNF, and Far -field - PWNF), Common Shiner fish tissue mercury concentrations continue to remain below the consumption guideline value for sensitive populations (0.5 mg/kg, MECP 2015) PWREF and PWFF concentrations were below the working MECP SDB guideline for the protection of fish-eating wildlife of 0.2 mg/kg and PWNF concentrations were at or near that guideline.

- Common Shiner fish tissue mercury concentrations were influenced by a combination of sample location, fork length and sample year. Despite being below the 0.5 mg/kg consumption guideline, PWNF has consistently higher mean tissue mercury concentrations than PWREF; its MOD relative to PWREF is consistently above 25% based on multiple models (pairwise comparisons from a 2022-data ANOVA model and ANCOVA model and from a 2019–2022 ANCOVA model).

- The second species for tissue mercury concentration analysis, Central Mudminnow, had nearly half the mean tissue mercury concentration of Common Shiner at the same sites but reflected and confirmed the same relative differences between PWNF and PWREF as Common Shiner.

7.2 Recommendations

The below are suggestions to modify or improve the program.

1) Assess the timing and frequency for the collection of surface water for mercury testing. Total and Dissolved Mercury are typically less than their detection limits despite detections of methylmercury. A method with a lower detection should be investigated.

2) Continue to additionally sample Central Mudminnow for between-species comparisons across sites but increase the number of fish targeted to at least 10.

3) Further exploratory analysis of surface water constituent correlations and their correlations with fish tissue mercury concentrations may reveal drivers of differences between sites.

4) Investigate the feasibility of sampling sediment pore water for mercury constituents in order to develop a spatial model that describes site- and reach-scale variability in PWREF, PWNF, and PWFF sediments. Personal communications with RRM Environment Department Staff indicate the fragmented nature of sites from various causes such as beaver dams may lead to fish affinity or movement restrictions based on natural barriers.

5) Continue to monitor and augment the study as necessary based on the mine established discharge practices.
