Treasury Metals Revised EIS Report Goliath Gold Project April 2018

NOTE TO READER APPENDIX H

In April 2015, Treasury Metals submitted an Environmental Impact Statement (EIS) for the proposed Goliath Gold Project (the Project) to the Canadian Environmental Assessment Agency (the Agency) for consideration under the Canadian Environmental Assessment Act (CEAA), 2012. The Agency reviewed the submission and informed Treasury Metals that the requirements of the EIS Guidelines for the Project were met and that the Agency would begin its technical review of the submission. In June 2015, the Agency issued a series of information requests to Treasury Metals regarding the EIS and supporting appendices (referred to herein as the Round 1 information requests). The Round 1 information requests included questions from the Agency, other federal and provincial reviewers, and members of Indigenous communities, as well as interested stakeholders. As part of the Round 1 information request process, the Agency requested that Treasury Metals consolidate the responses to the information requests into a revised EIS for the Project.

Appendix H to the revised EIS (Acoustic Environment Study) includes information related to the effects of the Project on noise. The appendix includes the following four components:

- H-1: A memorandum from RWDI Air, dated May 5, 2017, which provides an opinion of the implications of refinements to the Project layout to the noise levels predictions presented as part of the original EIS. The expected changes should be relatively minor, resulting in slightly higher predicted noise levels for those receptors located along East Thunder Lake Road. The predicted noise levels at the closest receptors, located to the south of the Project near Tree Nursery Road are expected to be slightly lower as a result of the changes to the Project since the filing of the original EIS.
- H-2: Noise Baseline Study: This study presents the results of the monitoring program to measure and record background ambient sound levels at receptors in proximity to the Project, and to describe baseline noise conditions. The information contained in this report was relied on to prepare Section 5.3.1 of the revised EIS.
- H-3: Acoustic Assessment Report (AAR): This study demonstrates the Project will be able to
 achieve compliance with provincial permitting requirements. The information contained in this
 report was relied on as the primary source of information for the assessment of the effects of
 the Project on blasting noise and vibration levels (Section 6.4 of the revised EIS). The
 provincial permitting required to obtain a noise ECA is a separate process that will require
 Treasury Metals submit an updated AAR reflecting the final design specifications for the
 Project.
- H-4: Environmental Noise Assessment: This study provides an evaluation of the effects of the Project on noise levels throughout the life of the Project. The information presented in this report is the primary source of information used for describing the effects of the Project on noise levels (Section 6.4 of the revised EIS).

Treasury Metals Revised EIS Report Goliath Gold Project April 2018

- H-5: A memorandum from RWDI Air, dated March 12, 2018 providing technical details in support of information requests with respect to:
 - The definition of regional and local study areas;
 - o Inclusion of noise due to off-site project vehicle traffic;
 - Assessment of blasting noise; and
 - o Inclusion of adjustments for sound character.

No changes have been made to the portions of this appendix presented in the original EIS issued in April 2015 (i.e., H-2, H-3 and H-4), however memorandum's H-1 and H-5 have been provided to support technical information identified as deficient during the Round 1 Information Request process. To aid the reader, bookmarks for each component are provided in the electronic copy of this appendix.

As part of the process to revise the EIS, Treasury Metals has undertaken a review of the status for the various appendices. The status of each appendix to the revised EIS has been classified as one of the following:

- **Unchanged**: The appendix remains unchanged from the original EIS, and has been re-issued as part revised EIS.
- **Minor Changes:** The appendix remains relatively unchanged from the original EIS, and has been re-issued with relevant clarification.
- **Major Revisions**: The appendix has been substantially changed from the original EIS. A rewritten appendix has been issued as part of the revised EIS.
- **Superseded:** The appendix is no longer required to support the EIS. The information in the original appendix has been replaced by information provided in a new appendix prepared to support the revised EIS.
- **New**: This is a new appendix prepared to support the revised EIS.

The following table provides a listing of the appendices to the revised EIS, along with a listing of the status of each appendix and their description.

List of Appendices to the Revised EIS				
Appendix	Description			
Appendix A	Major Revisions	Table of Concordance		
Appendix B	Unchanged	Optimization Study		
Appendix C	Unchanged	Mining Study

Air Quality and Noise Impact Changes Related to Proposed Mill Location

Treasury Metals

RWDI has previously completed an Air Qualityⁱ and Noiseⁱⁱ assessment for the Environmental Impact Statement (Federal) as well as an Air Qualityⁱⁱⁱ and Noise^{iv} assessment for the Environmental Compliance Assessment (Provincial). There were numerous air quality and noise sources examined for the project and their impact was assessed at receptors around the site.

Treasury Metals has asked RWDI to review the impact of moving the mine mill and associated activities to a location roughly 500 metres the northwest of the previously proposed location as shown in Figure 1, attached. Relatively few of the air quality and noise sources are associated with the mill. Generally speaking, this move would be an improvement or neutral in terms of air quality and noise. The mill activities are now farther from the closest receptors to the site and will improve. The receptors to the west, near Thunder Lake, are all over two kilometers away from the mill activity and will now be approximately 250 metres closer to the mill activities and will be neutrally affected. The following sections examine the air quality and noise impacts related to the proposed relocation of the mill.

AIR QUALITY

Air Quality Sources

The locations of the sources used in the air quality modelling are shown in the figure following. The red rectangles indicate the approximate positions of the previously proposed position of the mill and the newly proposed location of the mill.

The following sources associated with the mill were evaluated in the EIS and/or ECA assessments:

Source	Label	Percentage Emissions
Road to ore stock pile (shorter)	ROAD2	2% of Airborne metals
Unloading from ore trucks	ORE2	< 1% of particulate
Loader feeding ore crusher	LOADER	< 1% of particulate
Dozer on ore pile	DOZER1	3% of particulate
Insignificant Sources		
500 KW Emergency generator	Gen1	
150 kW Emergency Generator	Gen2	

BAGHOUSE

ELUTION

KILN

MILL

Reference # 1602163 Page 2

Baghouse emissions -ore crusher

Kiln Burner

Elution Heater

Carbon Leach Tanks

The insignificant sources listed above will continue to be insignificant if the location of the mill is changed. For a further discussion of the significance of the sources we would direct the reader to the Air Quality Environment Compliance Assessmentⁱⁱⁱ. The only significant emission from the mill area that were assessed are related to particulate emissions.

Air Quality Receptors

The only receptors that could possibly be negatively affected by moving the mill are the receptors to the west of the mine site, towards Thunder Lake. The receptor locations are shown in the figure below which also shows the worst case 24-hour total suspended particulate (TSP) emissions:

The closest residential receptors are roughly 2500 metres from the initially proposed location of the mill. The newly proposed mill location will be approximately 300 metres closer to the western receptors.

Air Quality Impact Frequency

The receptors located to the west of the site are also only infrequently impacted by emissions from the mill. The figure below shows the distribution of wind angles for the area:

As can be seen from the wind rose above the western receptors will be downwind of the mill area less than 10 % of the time.

Air Quality Discussion

The mill site will be roughly 12% closer to the closest residential receptors to the west of the site. The receptors are well past the point of maximum ground level concentrations for the mill emissions. Numerical modelling of the mill emission would show concentrations at these points would increase less than 12%. Since mill area emissions only represent 7% of the total emissions, even if the predicted concentrations related to the emissions from the mill area doubled, they would only represent a 7% increase in the predicted concentration of particulate. The most critical air quality impacts modelled for the western receptors are related to the 24-hour TSP concentrations. Under worst-case conditions, at the closest

residential receptor, the changed mill location would translate to roughly 3 micrograms per cubic metre of TSP. Any increase in concentrations related to the newly proposed mill location would occur less than 10% of the time.

The worst case receptor locations were to the south of the mine property. These locations will experience lower concentrations as a result of the new proposed mill location. The same is true for any receptors to the east of the site. There are no nearby receptors to the north of the site.

In conclusion, the receptors to the west of the mine site would experience very small increases in particulate emissions that would occur infrequently and would still be below air quality criteria. Air quality will be improved at all other receptors as a result of the new mill location.

NOISE

The locations of the noise sources are shown in the figure following.

The next figure shows the noise modelling results with mill located in the previously proposed location as well as a number of critical receptors.

The receptor that will be most negatively affected by moving the mill related noise sources 500 metres to the northwest will be NR30. The mill will be roughly 300 metres closer to NR30. The table following shows the impact of all the mill related noise sources at NR30.

The impact of all the mill related sources at NR30 is 17 and 28 decibels for regular and emergency operations respectively. The new proposed mill location is roughly 300 metres closer to NR30. The average distance of the mill related sources is 2515 metres from the previously proposed mill location. The simple noise to distance attenuation is calculated by the formula:

20 log (R2/R1)

Where: R1 is the distance to the first receptor from the source

R2 is the distance to the second receptor from the source

Thus:

20 log (2515/2215) = 1.1 dBA

The approximate impact at NR30 from the sources related to the new mill location is 29 dBA. The modelled noise impact from all sources at NR30 was 34 dBA with the mill in the new location the impact from all sources will be below 35 dBA which is still well below the provincial nighttime guideline of 40 dBA.

Please note that the 1.1 dBA increase is only related to the mill sources. The impacts at NR30 are still dominated by other sources so the cumulative increase is much less than 1.1 dBA.

The previously modelled impact at NR3, which is the closest receptor to the site, was 40 dBA. The old mill location was within one kilometer to NR3 and the new location will be roughly 1200 metres away. The noise impact will likely be below 40 dBA at this location now.

In conclusion, the proposed new mill location will not cause any of the critical receptors to be above noise criteria values and may improve conditions at the worst-case receptor.

CLOSING

In general, the new proposed mill location will have benefits in terms of air quality and noise at the most greatly impacted receptors.

Those receptors that will now be closer to the mill will have imperceptible changes in noise impacts. All receptors will be below noise criteria.

In terms of Air Quality (particulate) impacts, the receptors to the west will infrequently experience very small increases in particulate levels over what was predicted with the old mill location. The predicted levels will still be well below Air Quality criteria.

Yours very truly,

1. INTRODUCTION

Treasury Metals Incorporated (Treasury) has been exploring and developing the Thunder Lake Gold deposit known as the Goliath Gold Project (the Project), located near Dryden, Ontario in the Kenora Mining District (Figures 1 and 2). Treasury continues to develop the Project towards Feasibility Status through: Environmental Baseline Studies which were initiated in Fall of 2010 and are ongoing.

The purpose of this report is to summarize the existing baseline conditions in the study area of the Project in terms of environmental noise.

1.1 Overview of Goliath Gold Project

The Project is located in northwestern Ontario, approximately 125 kilometers (km) east of the City of Kenora, 20 km east of the City of Dryden and 325 km northwest of the City of Thunder Bay. The total area of the Project is 4,991 hectares (50 km²) covering portions of Hartman and Zealand townships east of the city of Dryden, Ontario.

Treasury has undertaken a 30,000 meter diamond drill program and has several development stage programs underway at the Project. In 2010, A.C.A. Howe International completed an Independent Preliminary Economic Assessment on the deposit and made recommendations for the further project development.

Treasury began an exploration program in 2008 and has not previously undergone any environmental or advanced exploration/mine permitting processes. No other exploration work has been completed on the Thunder Lake Property or the Laramide Property since 1999 and 1994, respectively. Underground and diamond drill hole sampling has previously taken place at both properties (A. C. A. Howe, 2010).

The proposed mining development is focused on the Thunder Lake Deposit. Operations will start initially with surface methods and follow with underground mining production from Year 3 to Year 10. A mill with gravity separation followed by carbon-in-leach circuit (CIL) is proposed for mineral processing (A. C. A. Howe, 2012).

2. ENVIRONMENTAL NOISE

Environmental sound levels vary continuously over time. To account for both daily and short-term variations in sound levels, several single numerical descriptors have been developed based on large-scale psycho-acoustic studies of annoyance with environmental noise. These allow sound monitoring to be conducted for a constantly varying sound environment over an extended period, with the results described as a single number that accurately describes the environment.

The single number descriptor commonly used in most international standards for environmental sound measurements is the energy equivalent sound level (L_{EQ}). The L_{EQ} value, expressed in dBA, is the energy-averaged, A-weighted sound level for the complete measurement interval. It is the steady, continuous sound level over a given period that has the same acoustic energy as the actual varying

sound levels occurring over the same period in the measured environment. It is one of the most common and useful predictors of human response to noise, and is also one of the noise descriptor that is used in the majority of environmental sound level criteria. The A-weighting accounts for the frequency content of the measured sound based on a frequency response similar to that perceived by the human ear.

The descriptors specific to this study are $L_{EQ\ 1-hr}$, L_{MAX} and L_{MIN} . The $L_{EQ\ 1-hr}$ is the 1-hour A-weighted energy equivalent sound level, $L_{EQ\ 1-hr}$, referred to as the hourly sound level. The L_{MAX} is the maximum sound level experienced during the monitoring program. The L_{MIN} is the minimum sound level experienced during the monitoring program.

Ranges of typical everyday sounds are presented in Table 1.

Table 1: Typical Ranges of Commonly Encountered Sound Levels

Sound Level	dBA	Common Everyday Sources
b _l	120	Threshold of pain
enir	115	Maximum noise level at a hard rock concert
Deafening	110	Accelerating motorcycle at 1 m
Q	105	Loud auto horn at 3 m
p	100	Dance club; Maximum human vocal output at 1 m
Lot	95	Jackhammer at 15 m
Very Loud	90	Inside a noisy factory
>	85	Heavy truck pass-by at 15 m
	80	School cafeteria; Noisy bar
Pnoq	75	Near edge of major highway; Inside automobile travelling at 60 km/h
o P	70	Vacuum cleaner at 1.5 m
	65	Normal human speech, i.e., an un-raised voice, at 1 m
е	60	Typical background noise levels in a large department store; Hair dryer
Moderate	55	Running tap water
lode	50	Clothes dryer; Air conditioner
2	45	Typical background noise level in an office caused by HVAC; Flowing stream
	40	Typical background noise level in a library; EUB guideline for noise at 1.5 km
Faint	35	Average whisper; Typical quiet outdoors
Еа	30	Broadcast studio
	25	
	20	Deep woods on a calm day
aint	15	
Very Faint	10	
Ver	5	Human breathing
	0	Threshold of hearing, i.e., quietest sound that can be heard

3. ASSESSMENT CRITERIA

In Class 3 areas, described as rural or recreational, the applicable MOE "Stationary Source" guidelines are those set out in MOE Publication NPC-232 (MOE, 1995). These guidelines state that one-hour sound exposures (L_{EQ}, _{1-hr} dBA values) from stationary noise shall not exceed that of the background, where the background is defined as the sound level present in the environment produced by noise sources other than those associated with the facility under assessment. The MOE Publication NPC-232 sound level limits are outlined as follows:

- The higher of 45 dBA or background noise, during the daytime hours (0700-1900h);
- The higher of 40 dBA or background noise, during the evening hours (1900-2300h); and
- The higher of 40 dBA or background noise, during the night-time hours (2300-0700h).

The applicable guideline limit is the higher of the measured background sound level and the MOE's minimum sound level limit. The above default sound level limits are the applicable for the receptors surrounding the Project. Background ambient sound level measurements were conducted and are summarized in Section 4.

4. BASELINE SOUND LEVEL ASSESSMENT

The basic procedures for the baseline assessment consists of long-term background sound level measurements of receptors near the Project, validation of measured hourly data based on weather information, and comparing the validated lowest hourly sound level data to the default guideline limits.

Long-term measurements of background ambient sound levels at one location was conducted from December 5 to December 7, 2011, near the Project Site noted in Figure 1. Additional monitoring at three representative locations was conducted from July 3 to July 9, 2013, shown in Figure 2. All measurements were conducted in accordance with the applicable requirements of MOE Publication NPC-103 (MOE, 1977b).

4.1 Equipment

Sound level readings were obtained using a Larson-Davis Model 820 precision integrating sound level meters, configured to log L_{EQ} (5 minute) levels during the 2011 monitoring and configured to log L_{EQ} (1 hour) levels during the 2013 monitoring. This unit meets IEC 61672 (IEC, 2002) Class I sound level meter requirements, and Ontario Ministry of the Environment Publication NPC-102 requirements (MOE, 1977a). The sound level meters were field-calibrated at the beginning and end of measurements to ensure accuracy for all monitoring events.

A PCB Model 377A60 microphone was used at each monitoring location to ensure adequate low-level response (with a "noise floor" of approximately 20 dBA). Each microphone was mounted on a tripod, with the microphone located approximately 1.5 m above grade. Environmental microphone kits were used to provide protection from wind and rain. Each kit includes a wind screen with bird spikes to reduce wind

noise and interference from birds. Desiccants were used to sustain dryness of the environmental kit to prevent damage from rain.

Weather data were obtained from the nearest Environment Canada meteorological station located in Dryden, Ontario. This station recorded wind speed, wind direction, temperature and relative humidity on an hourly basis.

4.1.1 Data Validation

Data collected from the sound level meters were analyzed to determine the baseline conditions. Only data with meteorological conditions complying with MOE NPC-103 criteria during the measurement period have been used in the analysis of background sound levels. Acceptable meteorological conditions are shown in Table 2.

Table 2: Acceptable Meteorological Conditions

Parameter	Lower Limit	Upper Limit
Temperature	-20°C	40°C
Wind Speed	-	20 km/h
Relative Humidity	-	95 %
Precipitation	-	0 mm/h

Periods of short duration high-level events resulting from human activity or wind gust are excluded from the analysis. Audio recording was not conducted as part of this program and, therefore validation of the activities during these short duration high-level events was not possible. The measured sound levels from these events were excluded from the analysis. This is a conservative approach to determining the lowest background sound levels. Highway traffic noise from the Trans-Canada Highway was steady resulting in a continuous background sound and was therefore not excluded for the 2011 analysis.

5. BASELINE MONITORING RESULTS AND DISCUSSION

The study area is in a rural location outside a small northern community with low levels of human activity. Background ambient sound levels in remote areas are typically low, ranging from about 25 to 40 dBA. These values are similar to those measured for the Project. Tables 3 and 4 show the measured ambient noise values for each monitoring event. Each table summarizes the measured ambient sound levels and the resultant guideline limits. The sound from these levels would be described as faint (see Table 1). The measured ambient sound levels are lower than the NCP-232 guideline minima; therefore, for the purposes of this study, the NCP-232 guideline minima will be used as the sound level criteria for the detailed impact assessment.

Table 3: 2011 Baseline Monitoring Results

	L _{EQ} (1hr)	Min	Max	NPC-232 Guideline Minima	Resultant Limit
Day	28	20	54	45	45
Evening	34	23	50	40	40
Night	30	19	66	40	40

Noise observed during the study consisted of most wind, small animals, bird noise and noise from the TransCanada Highway which runs in near proximity to the study area. The difference between daytime and nighttime sound levels were generally small, and are attributed mainly to very low level of noise from human activity which could not be screened out. Figures 3 through 5 graphically display the measured LEQ, LMIN and LMAX for the duration of the 2011 study.

Table 4: 2013 Baseline Monitoring Results

Location	Time Period	L _{EQ} (1hr)	L _{MIN} (1hr)	L _{MAX} (1hr)	MOE NPC-232 Guideline Minima	Resultant Limit
	Day	39	30	70	45	45
Site 1	Evening	38	30	66	40	40
	Night	35	29	67	40	40
Site 2	Day	38	20	68	45	45
	Evening	37	27	63	40	40
	Night	32	19	68	40	40
Site 3	Day	32	21	69	45	45
	Evening	35	24	69	40	40
	Night	28	20	62	40	40

Notes: Daytime time period – 0700-1900 hours
Evening time period – 1900-2300 hours
Night time period – 2300-0700 hours

Figures 6a through 8c graphically display the measured L_{EQ} , L_{MIN} and L_{MAX} with weather exclusions for the duration of the 2013 study at each of the three locations.

6. CONCLUSION

This report has presented a summary of the current noise levels in the vicinity of the Project site. The noise measurement results indicate that the existing baseline sound levels did not exceed the sound level limits as outlined in the MOE Publication NPC-232. Based on our review of the data, it appears that the existing baseline conditions are typical of Northwestern Ontario conditions.

Acoustic Assessment Report Treasury Metals Incorporated – Goliath Gold Project RWDI#1401701 October 16, 2014

EXECUTIVE SUMMARY

Treasury Metals Incorporated retained RWDI AIR Inc. to complete an Acoustic Assessment Report in support of the Goliath Gold Project. The Project is a proposed gold mine near Wabigoon, Ontario. This assessment has been completed in support of an application for an Environmental Compliance Approval with Limited Operational Flexibility.

This assessment focuses on sound emissions from sources at the facility and their potential effect on worst-case sensitive receptors surrounding the facility. Sources at the facility include: ventilation equipment, process exhausts, mobile heavy equipment, and rock crushing equipment. Data for the predictable worst-case operations were described using one operating scenario representative of a predictable worst-case hour during the worst-case project year. Sound levels from the facility were assessed by detailed modelling using the Cadna/A software package. Airborne and Ground-borne vibrations due to blasting activities were assessed using guidance from NPC-119 (MOE, 1977) and Guidelines on Information Required for the Assessment of Blasting Noise and Vibration (MOE, 1985).

Modelling inputs include source type and locations, and sound levels. Source types and locations were taken from information provided in the Goliath Gold project description, and from Treasury Metals personnel. Sound levels were taken from information on file at RWDI, or were calculated based on equipment specifications. At this early stage of development, information can be limited therefore, where necessary, modelling has been conducted using sound levels for typical sources at a mine.

Noise sensitive receptors identified in the area are houses (seasonal or otherwise). Forty-four individual receptors were identified. Noise modelling software was used to predict the effects of the Project at the nearest receptors, representing the worst case impacts.

In some circumstances, sound levels of specific sources were found to cause noncompliance at noise sensitive receptors. Quieter than average equipment will be required for some pieces to achieve compliance. This equipment is commercially available. Treasury Metals has committed to ensuring that sound levels from these pieces of equipment meet these requirements.

Vibrations from blasting activities is predicted to be in compliance with NPC-119 at all sensitive receptors Based on the commitment described above to limit sound levels of certain equipment, the Goliath Gold Project is predicted to be in compliance with the Ministry of Environment and Climate Change guidelines at all receptors.

1. INTRODUCTION

Treasury Incorporated has retained RWDI AIR Inc. (RWDI) to complete an acoustic assessment and Acoustic Assessment Report (AAR) for the Goliath Gold Project (the Project) located near Wabigoon, Ontario. This AAR is completed using the applicable MOE guidance documents (MOE, 2012 and MOE, 1995). A copy of the Acoustic Assessment Report checklist is included in Appendix A. This assessment has been completed in support of an application for an Environmental Compliance Approval with Limited Operational Flexibility.

The MOECC Primary Noise Screening has been completed for this facility, and is included in Appendix A. The NAICS code for this facility is 21222. A detailed assessment is required because sensitive receptors are located within the setback distance provided by the Primary Noise Screening. All land within several kilometers of the Project is crown land, or is unincorporated land, and therefore has no zoning information available.

This assessment focuses on sound levels due to the Project at surrounding worst-case sensitive receptors. Sources at the facility include: ventilation equipment, building exhausts, on site vehicle traffic, and rock crushing equipment.

Operations at the Project do not include large sources of vibration, with the exception of blasting activities. An evaluation of blasting activities is included in section 6.

2. FACILITY DESCRIPTION

Treasury Metals Incorporated (Treasury) has been exploring and developing the Thunder Lake Gold deposit known as the Goliath Gold Project (the Project), located near Wabigoon, Ontario. The Project involves the construction, operation, closure, and reclamation of a 4.5 million tonne-per-annum (Mt/a) open pit and underground mine that will operate for approximately 15 years. The site includes three open pits that will be mined sequentially, a mill building for ore processing and a tailings area. With the exception of blasting and generator testing, which will occur during daytime hours only, all noise sources associated with the Project may operate 24 hours a day, seven days a week.

Construction and Site Preparation phases will include tree clearing, grubbing, stripping of overburden, crushing of aggregate for road construction, blasting, and construction of project facilities. The duration of the Site Preparation and the Construction phase is estimated to be 3 years. The majority of noise sources during this phase will be mobile equipment operating at grade.

The operations phases will include both underground and open face mining activities. The open face mining activities include drilling, blasting, dozing, excavating and the transportation of rock material around site. The underground activities include the operation of intake and exhaust vent raises and the transportation of rock material to the surface. The processing plant, or mill, will include several stationary noise sources related to ventilation and process exhausts. Emergency power generators are to be tested only during the daytime hours. The duration of the operations phase is estimated to be 10 years.

Closure, Decommissioning and Restoration phases will include backfilling and flooding of the open pits and underground mine area, disassembling of infrastructure and equipment as well as overall site maintenance. The duration of the Closure, Decommissioning and Restoration phase is estimated to be 2 years. The majority of noise sources during this phase will be mobile equipment operating at grade.

3. NOISE SOURCE SUMMARY

Details regarding types of equipment used during the operations phase were limited at the time of this assessment. Best-available data regarding noise sources for future construction, operations, and decommissioning were collected from Treasury Metals, and used to predict sound levels for the Project. The significant sources were identified from drawings and the project description provided to RWDI by Treasury. No significant impulsive sources were identified with the exception of blasting which is assessed separately.

3.1 Insignificant Sources

At the time of assessment, detailed drawings for construction had not been developed. Details of small exhausts serving areas such as break rooms, washrooms, and storage areas were therefore not available. Such sources typically have sound power levels less than 80 dBA and were considered to be insignificant. A small amount of comfort heating and cooling has also been considered to be insignificant.

Movements of light vehicles (pickup trucks, vans, cars, etc.) traveling on site are unpredictable. With the limited operating times of these vehicles, and relatively low power levels compared to other sources on site, these sources have been considered insignificant. A weekly armored vehicle trip removing gold from the site has similarly been considered insignificant.

A summary of modelled sources is included in Table 1 in the tables section; detailed source information is included in Table B.1 of Appendix B. Source locations are shown in Figure 1.

3.2 Continuous Sources

Sound power level data for continuous sources was obtained by measurements, engineering calculations, manufacturer's data, and sound levels for similar equipment on file at RWDI.

Sound pressure level (SPL) measurements were conducted for the operation of an exploration drill during a site visit on April 22, 2014. This data was used to represent the operations drills, sources OP_DRILL1_o and OP_DRILL2_o). Sources (OP_DRILL1_o and OP_DRILL2_o) were both time-weighted to operate for 30 minutes per hour in order to provide a realistic representation of drilling operations on site. All measurements were consistent with ISO 3744:1994(E) (ISO, 1994a), and ISO 3746:1995(E) (ISO, 1995) measurement standards, and the applicable portions of the MOE Publication NPC-103 (MOE, 1978). The measured SPLs were converted into PWLs based on measurement distances and the size of the equipment being measured, as appropriate.

The sound power levels for the dewatering pump, and aeration tank blower (sources OP_Dpump1_o, and ML_Blwr_o) were calculated based on typical specifications and information provided by Treasury. The dewatering pump was calculated with the pump operating at 180m water column of static pressure. This is the representative sound level of the pump when the pit is at its deepest level of excavation, and conservative for when the pump is near ground level. Calculations of source sound power level and octave band spectra for the aeration tank blower and the dewatering pump were made using equations provided by Crocker (Crocker, 2007) and Bies and Hansen (Bies, 2009) respectively. Calculations are shown in Appendix B.

The sound power level for the exhaust louvers on the mill building (sources ML_ExLvr01_o through ML_ExLvr14_o) were calculated assuming an indoor sound power level of 85 dB within the mill facility. This is a typical objective for indoor sound levels in order to comply with occupational health and safety regulations. The locations of these sources were unknown and thus the sources were distributed evenly around the building. The number of exhaust openings was calculated based on a minimum of 6 air changes per hour, and based on the approximate volume of the building. The sound power level of these sources includes the sound from a fan in each opening, sized to accommodate the required air changes. The fan sound power level was calculated using equations from Crocker (Crocker, 2007). Each modelled point source includes indoor noise radiating through an intake, indoor noise radiating through an exhaust, and the sound from a fan at the exhaust opening.

The PWLs for the generators, kiln fan and intake and exhaust vent raises (sources Gen150_e, Gen600_e, ML_KF_o, UG_ExVentRaise1_o, UG_ExVentRaise2_o and UG_VentRaise1_o respectively) were approximated based on the manufacturer's PWL data for similar equipment. The sound power level data for UG_VentRaise1_o and UG_ExVentRaise1_o was taken from a manufacturer data sheet for a fan similar to that which would typically be used for this purpose. At UG_ExVentRaise2_o these sound power levels were found to result in noncompliance. The sound level of the fan has been reduced by 5 dB for UG_ExVentRaise2_o. Treasury Metals is committed to selecting equipment which is less than or equal to the sound power level used in the modelling for this source. The manufacturer's PWL data is included in Appendix B.

The sound data used for following sources were taken from measurements of similar equipment on file at RWDI.

- Rock drop from trucks and loaders (sources ML_Rckdrp_o, OP_Rckdrp_lowgrade_o, OP_Rckdrp_overburden_o, and OP_Rckdrp_waste_o);
- Front End Loader (source ML ldr o);
- Bulldozers (source OP_DZR_lowgrade_o, OP_DZR_overburden_o, OP_DZR_waste_o);
- Jaw crusher (source Crshr);
- Hydraulic Excavators (sources OP_Excvtr1_o, OP_Excvtr2_o); and
- 50 Ton Haul Trucks (sources Htruck1 o, Htruck2 o, Htruck3 o).

The evaluation of noise impacts is based on the principle of worst-case hour. Where sources operate for less than an hour, the sound level of the source is weighted to account for reduced operation. Sources (OP_DZR_lowgrade_o and OP_DZR_overburden_o) were time-weighted at 30 minutes per hour to account for the dozer operating at both the low grade and overburden stockpiles in a given worst-case hour. The front end loader at the run of mine pad is limited to operating 30 minutes per hour. This is due to the periodic nature of rock material drops offs at the pad. Rock drop noise represents the noise from rocks being dumped from trucks and loaders. This activity was time weighted, as it is periodic. Details on time weighting for all sources are provided in Table B.1.

In some circumstances, sound levels of specific sources modelled from data on file were found to cause noncompliance at noise sensitive receptors. This data is representative of average equipment, and does not represent quieter equipment currently available. Quieter than average equipment will be required for some pieces of heavy equipment to achieve compliance. Treasury Metals has committed to ensuring that sound levels from these pieces of equipment meet these requirements. PWLs of all equipment are outlined in Appendix B, and every effort will be made to ensure that selected equipment has sound emissions equal to or lower than the PWLs specified there.

Haul trucks traveling on site were modelled using a moving point source calculation method. A total of 14 round trips are expected in a worst case hour between the open pit, and any combination of the waste rock stockpile, low grade stockpile, and run of mine pile. The route to the waste rock stockpile is considerably longer than all other routes, and results in the highest sound level at all receptors. These trips were conservatively weighted towards having most trips in a predicable worst-case hour routed to the waste rock stockpile. Ten trucks were modelled travelling round trip between the open pit and waste rock stockpile for a total of 20 truck movements along this route. Two trucks were modelled travelling round trip between the open pit and the low grade stockpile. Two trucks were modelled travelling round trip between the open pit and run of mine pile in any worst-case hour for a total of 4 truck movements along the route. Trucks are expected to travel on the site at a speed of 30 km/h.

Measurement data and details of the SPL to PWL conversions, octave band sound power data, and manufacturer's data are included in Appendix B. Weather conditions and measurement equipment for measurements of exploration drilling are in compliance with the requirement set out in MOE Publication NPC-103 (MOE, 1978). The measurement weather conditions are summarized in Appendix C. Measurement equipment model and serial information is provided in Appendix C.

3.3 Identifiable Source Characteristics

Sources that have characteristics considered to be particularly annoying receive additional consideration in accordance with NPC-104 guidelines (MOE, 1978). The adjustment is based on assessment at the point of reception, as described in Publication NPC-103. No sources were identified to exhibit annoying sound emissions.

& SCIENTISTS

Page 5

3.4 Operating Scenarios

The assessment of noise focuses on the predictable worst-case hour, during a worst-case year in the life of the Project. Based on modelling conducted for the federal Environmental Assessment, it is expected that the worst-case phase is the operating phase; the construction and decommissioning phases are predicted to generate lower sound levels. The early years which occur during the operations phase are the worst-case in the operations phase, due to an increase in activity related to the construction of the underground mine and a lack of screening from pit sources.

As an absolute worst-case during the early years of the operations phase, all sources related to the open pit mine have been modelled at grade, along with the vent raises for the underground mine operating. This discounts all shielding effects from the ultimately 180 m deep pit, and conservatively assumes that the vent raises will be operational while open pit mining is still near the surface. These conservative estimates of the worst-case operations were chosen to account for unknowns such as remediation of the open pit during underground mining activities. Those sorts of activities are anticipated to generate lesser noise than the modelled scenario.

Two emergency generators located at the site will be tested on a regular basis, during daytime hours only. With the exception of blasting, all other sources as described above may operate 24 hours per day. Two scenarios have therefore been modelled: operating phase, excluding generators, and including both open pit and underground sources, and generator testing.

4. POINT OF RECEPTION SUMMARY

Sound levels from sources at the Project were determined at points of reception (PORs) located on noise-sensitive land uses. Noise-sensitive land uses are defined in the MOECC's environmental noise guideline, publication NPC-300 (MOE, 2013), as the property of a person that accommodates a dwelling, a noise-sensitive commercial building or a noise-sensitive institutional building. Vacant lots are considered noise-sensitive, provided they are zoned to allow a sensitive use and are accessible by road. A noise-sensitive land use may have one or more receptors.

PORs for an acoustic assessment are those locations where sound from the facility is received and assessed against the applicable limits. Sound levels may be assessed at the façade of the building and/or outdoor areas, depending on the type of sensitive land use assessed. Outdoor PORs are only assessed for dwellings and are not assessed for commercial and institutional noise-sensitive land uses.

Residential receptors include houses, cottages, and the like, whether continuously occupied or seasonal. For existing residential properties, sound levels are assessed at the façade of the building at a height of 4.5 m above local grade and an outdoor POR at a height of 1.5 m. The point of assessment for the outdoor receptors is a point 30 m from the building façade, or the property line in cases where the 30 m setback would exceed the size of the property.

Commercial and institutional receptors include hotels, churches, daycares, schools, clinics, and the like. The point of assessment for these types of receptors is at the façade of the building only; Outdoor receptors are not assessed for commercial and institutional noise-sensitive land uses.

Properties that are zoned to permit a noise-sensitive land use, but are currently vacant need to be assessed as if a noise-sensitive land use exists at that location. For these noise sensitive areas, the receptors are typically considered in a location consistent with typical local building patterns, at a height of 4.5 m above local grade. In the case of unincorporated land without a minister's zoning order, the land is generally understood to allow noise-sensitive uses, and would be assessed in the same way as land that is zoned for a noise sensitive use. All land within the vicinity of the Project is either crown land, or unincorporated land. No zoning information is available for these areas.

There is currently a house located to the West of the low grade stockpile which is owned by Treasury Metals, and will not be occupied during the life of the Project. A house located on the north west corner of Normans Rd and Nursery Rd is also owned by Treasury Metals and will not be occupied during the life of the Project. The house located approximately 400 m east of the intersection of Normans Rd and Nursery Rd, on the North side of Normans Rd is currently occupied, and will be vacated prior to the commencement of the Project.

Vacant land on the south side of Normans Rd, immediately to the south of the low grade stockpile is apparently accessible by road as judged from aerial photographs. This section of Normans Road, west of Nursery Rd, is controlled by Treasury Metals, and will result in this land being inaccessible for the life of the Project.

Forty-four individual noise-sensitive receptors were identified within the local study area. Where the surface mining rights have been secured by Treasury Metals, land use was assumed to be non-noise-sensitive and no receptors were identified. All other vacant lands in the vicinity of the Project that were found to be inaccessible (except by a rough cut-in through the forest) were not considered as receptors. Forty-two of the receptors were identified as houses. One was identified as the campground at Aaron Provincial Park. One receptor is a trailer located on otherwise vacant land. There are no receptors identified roughly within 2 km to the north or 8 km to the east, because Treasury Metals has surface rights to all land in those directions.

Since noise impacts decrease with distance from the source, the nearest receptors to the Project are considered the worst-case, and are evaluated explicitly. Other receptors are not evaluated explicitly, but effects can be seen noise contour maps. Figure 2 presents receptors that are explicitly evaluated.

5. ASSESSMENT CRITERIA

5.1 Exclusion Limits

The applicable guideline limits for the receptors in the vicinity of the Project are the "Stationary Source" guidelines for Class 3 area, set out in MOE Publication NPC-300. These guidelines state that one-hour sound exposures (A-Weighted hourly L_{EQ} values) from stationary sources in Class 3 area shall not

exceed that of the background, where the background is defined as the sound level present in the environment produced by sources other than those associated with the project under assessment. The MOE Publication NPC-300 minimum sound level limits at the façade (or plane of window) are summarized as follows:

- The higher of 45 dBA or background sound, during the daytime hours (0700-1900h);
- The higher of 40 dBA or background sound, during the evening hours (1900-2300h); and
- The higher of 40 dBA or background sound, during the nighttime hours (2300-0700h).

The MOE Publication NPC-300 sound level limits at an outdoor POR are applicable during the daytime and evening hours only. These limits are summarized as follows:

- The higher of 45 dBA or background sound, during the daytime hours (0700-1900h); and
- The higher of 40 dBA or background sound, during the evening hours (1900-2300h).

The applicable criterion is the higher of the background sound level and the default minimum sound level limit. Background sound level measurements showed levels below the exclusionary limits. The minimum sound level limits are therefore applicable.

Sound from the operation of emergency equipment, such as generators, is not considered except during planned testing. Sound levels of planned testing of emergency equipment are evaluated separately from all other noise from the Project. In the case where multiple pieces of emergency equipment are tested together, their combined impact is evaluated against the limit. The sound level limits for emergency equipment operating in a testing scenario are 5 dB greater than the sound level limits presented above.

5.2 Blasting

Blasting is evaluated separately under MOECC guidelines. Guidance for noise from blasting is taken mainly from two publications, NPC-119 (MOE, 1978) and Guidelines on Information Required for the Assessment of Blasting Noise and Vibration (MOE, 1985).

Blasting activities are identified as a source for sound due to airborne vibration (concussion). The level of sound experienced at a receptor is assessed using the peak pressure level measured in linear (un-weighted) decibels (dB). MOE publication NPC-119 introduces two limits, the cautionary limit, and the peek pressure level limit. The cautionary limit is 120 dB and can be applied in cases where there is no monitoring of sound levels from blasting. The peek pressure limit is 128 dB, and can only be used when sound level monitoring is conducted during blasting. The cautionary limit is used as the criteria for airborne blast noise for the Project.

Blasting activities are also identified as a source of groundborne vibration. Groundborne vibration is evaluated as a peak particle velocity measured in cm/s. NPC-119 limits vibration from blasting to 1.00 cm/s at a sensitive receptor location. For this assessment, sensitive receptors for vibration impacts are considered to be the same as those described in section 4 for noise.

6. IMPACT ASSESSMENT

6.1 Assessment of Sound Levels

The facility sound emissions were modelled based on the normal facility operations and emergency equipment testing operating scenarios as described in Section 3. The Sound Pressure Level (SPL) at surrounding PORs were calculated by modelling the sound propagation from the significant sources at the facility. The modelled SPLs at the PORs were assessed against the applicable sound level limits.

6.1.1 Continuous Sources

Modelling of sound level propagation for continuous sources to the receptors was conducted using Cadna/A, a commercially available implementation of the ISO 9613 (ISO, 1994b and ISO, 1996) algorithms. Cadna/A is produced by Datakustik GmbH. The modelling took into account the following factors:

- Source sound power level and directivity;
- Distance attenuation;
- Source-receptor geometry including heights, elevations and topography;
- Barrier effects of the site and surrounding buildings;
- Duration of events:
- Ground and air (atmospheric) attenuation; and
- Meteorological effects on sound propagation.

A sample calculation showing step-by-step calculation parameters is provided for receptor NR03, and is included in Appendix D. Key modelling parameters are summarized in Appendix D.

The individual contributions of each source at the modelled PORs are presented in Table 2. Sound level contours (isopleths of equal sound level) were generated for normal facility operations and for generator testing and are presented in Figures 3 and 4 respectively.

The SPLs at PORs under regular facility operations and emergency equipment testing scenarios were assessed using the applicable sound level limits, as shown in Table 3a and 3b, respectively. The predicted facility-attributable levels at each POR are in compliance with the applicable limits.

6.1.2 Blasting Noise

Modelling of blasting sound levels was conducted using numerical modelling techniques presented in the International Society of Explosives Engineers Blaster's Handbook (ISEE, 2011). Airborne vibration due to blasting activities attenuates from a site at a slower rate than ground vibrations. The distribution of this air vibration energy from a blast is also strongly influenced by the prevailing weather conditions during the blast. Other factors influencing airborne vibration propagation include:

- charge-weight per delay;
- depth of burial;
- volume of displaced rock;
- delay time intervals;
- type of explosive;
- atmospheric conditions; and,
- topography.

Further definition of these terms is provided in Appendix B.

The rate at which blast noise decays or attenuates from a blast site is dependent upon the scaled distance as follows:

- scaled distance (SD₃) = R/ $_3\sqrt{W}$
 - o where R = distance (metres) from the blast to a point of interest; and,
 - W = charge-weight (kilograms) detonated within any 8-millisecond delay period.

Prediction of maximum blast noise was based on the following equation which assumes average burial of the explosive:

- $P = 37.1 \times SD_3^{-0.97}$
 - o where P = peak air pressure (Pascals); and,
 - \circ SD₃ = scaled distance (metres per kilogram [m/kg^{1/3}]).

This equation produces a pressure in pascals, which is then converted to decibels (dB) as shown in the following equation:

- dB=20 log(P/P_o)
 - o where P_o is the reference pressure (2 x 10⁻⁵ Pa).

Sound levels from blasting were evaluated separately from sounds due to continuous noise sources as per the guidance. Levels were assessed at the five worst-case receptors as discussed in section 5.2. A radius of influence was also determined, which is the distance from a blast where the sound levels will fall off to the precautionary limit. The radius of influence is 95 m in all directions from the blasting. Any receptor further than 95 m from a blast will therefore experience effects lower than the NPC-119 precautionary limit.

All levels at receptors are predicted to be in compliance with the NPC-300 minimum sound level limits for a class 3 area. The predicted sound levels and applicable limits are presented in Table 3C.

6.2 Assessment of Vibration Levels

Ground vibration was calculated to determine the peak particle velocity in mm/s due to the blast. The rate at which ground vibrations decay or attenuate from a blast site can be expressed by the scaled distance, which is defined as:

- scaled distance (SD₂) = R/√W
 - o where R = distance (m) from the blast to a point of interest; and,
 - o W = charge-weight (kilogram) detonated within any 8-millisecond delay period.

The prediction of maximum ground vibrations can be calculated based on the following equation (ISEE 2011) for upper bound construction industries:

- PPV = 1730 (SD₂)^{-1.6}
 - where PPV = peak particle velocity (mm/s); and,
 - SD2 = scaled distance (meter per kilogram [m/kg1/2]).

Vibration levels for blasting are presented in NPC-119 and are limited to 1.00 cm/s. Using this limit, the area of vibration influence for blasting was determined to be 457 m. The nearest receptors are located more than this distance away from areas where blasting is likely to occur, so blasting vibration is predicted to be in compliance with NPC-119 at all sensitive receptors. Details of the blasting vibration calculation are included in Appendix B.

7. CONCLUSIONS

A detailed assessment of the Project sound levels was completed by modelling the individual contributions of the significant sources at the representative receptors. Predicted facility sound levels and vibration levels from blasting are in compliance with the applicable guideline limits at each of the receptors for daytime, evening and nighttime operations with the inclusion of reduced sound level equipment for some sources. This assessment predicts that the Project is in compliance with the requirements of the NPC-300 and NPC-119 guidelines.

Table 1: Noise Source Summary

Treasury Metals Inc. - Goliath Gold Project, 1401701

Notes to Table:

"Table A1" in Appendix A of Basic CCofA Guide.

Wherever possible, the Source ID matches the identifiers used in the ESDM report. 1.

2. Sound Power Level of Source, in dBA, not including sound characteristic adjustments per

Source Location: O = Outside of building, including the roof, I = Inside of building 3.

Sound Characteristic, per NPC-104: 4.

-S = Steady- Q = Quasi-Steady Impulsive - B = Buzzing

- C = CyclicWhere annoying characteristics are audible at the source, but not at receptors, no penalty is applied and the characteristic

in this table is shown as "S". See section 3 of the report text for further details.

5. Noise control measures currently in place or specified in construction drawings:

- S = Silencer/Muffler

- L = Lagging- A = Acoustic lining, plenum - E = Acoustic enclosure - U = Uncontrolled

- B = Barrier

Where noise control measures are specified in construction drawings or were found on existing equipment, octave band sound power levels include the effects of the noise control measures. Noise control measures recommended in the mitigation section of this report are not included in this table.

Table 2: Point of Reception Noise Impact Treasury Metals Inc. – Goliath Gold Project, 1401701

Notes to Table:

"Table A2" in Appendix A of Basic CCofA Guide.

"Continuous" noise sources includes operating time corrections and sum of steady, quasi-steady impulsive, tonal, cyclical and buzzing noise sources, with appropriate penalties applied, in accordance with documents NPC-104 and NPC-300.

Wherever possible, the Source ID matches the identifiers used in the ESDM report.

Sound Level units:

- dBA = 1-hour energy equivalent sound level ($L_{a_0}(1-hr)$), in terms of A-Weighted decibels.

- dBAl = Logarithmic mean impulsive noise level (L_{abl}), in terms of A-Weighted decibels incorporating an impulsive time weighting.

Noise and vibration receptors representative of worst-case potential impacts have been selected. For the purposes of noise and vibration impact assessment, the following land uses (existing or zoned for future use) have been considered:

- permanent , seasonal, or rental residences
- hotels, motels and campgrounds
- nursing / retirement homes

- churches and places of worship

Table 3A: Acoustic Assessment Summary

Treasury Metals Inc. - Goliath Gold Project, 1401701

Notes to Table:

- "Table A3" in Appendix A of Basic CCofA Guide.
- 1. "Continuous" noise sources includes sum of steady, quasi-steady impulsive, tonal, cyclical and buzzing noise sources, with appropriate penalties applied, in accordance with documents NPC-104 and NPC-300. Impulsive and emergency noise sources are assessed seperately from continuous noise sources.
- 2. Daytime occurs from 0700-1900h. Evening occurs from 1900h-2300h. Nighttime occurs from 2300-0700h.
- 3. Worst-case cumulative sound level from all applicable sources operating.
- 4. Has an acoustic audit (as defined in Publication NPC-233) been conducted with source in place and operating?
- 5. Applicable worst-case NPC-300 sound level limit.
- 6. Performance limit (aka guideline limit) based on following:
 - C = Calculated based on road traffic volumes in compliance with NPC-206 requirements.
 - M = Measured based on monitoring for a minimum 48 hour period, in accordance with NPC-233 requirements.
 - D = Default guideline minima per NPC-300.

Table 3B: Acoustic Assessment Summary

Treasury Metals Inc. - Goliath Gold Project, 1401701

Notes to Table:

- "Table A3" in Appendix A of Basic CCofA Guide.
- "Continuous" noise sources includes sum of steady, quasi-steady impulsive, tonal, cyclical and buzzing noise sources, with appropriate penalties applied, in accordance with documents NPC-104 and NPC-300. Impulsive and emergency noise sources are assessed seperately from continuous noise sources.
- 2. Daytime occurs from 0700-1900h. Evening occurs from 1900h-2300h. Nighttime occurs from 2300-0700h.
- Worst-case cumulative sound level from all applicable sources operating.
- 4. Has an acoustic audit (as defined in Publication NPC-233) been conducted with source in place and operating?
- 5. Applicable worst-case NPC-300 sound level limit.
- 6. Performance limit (aka guideline limit) based on following:
 - C = Calculated based on road traffic volumes in compliance with NPC-206 requirements.
 - M = Measured based on monitoring for a minimum 48 hour period, in accordance with NPC-233 requirements.
 - D = Default guideline minima per NPC-300.

NOISE SCREENING PROCESS FOR S.9 APPLICATIONS SUPPLEMENT TO APPLICATION FOR APPROVAL

In order to obtain an approval under Section 9 of the EPA, applicants are, as a minimum, required to assess and document the impacts of all noise emissions from their facility on any noise sensitive locations defined as a Point of Reception. In order to facilitate this assessment, the ministry has developed a Noise Screening Process.

The Noise Screening Process has been developed for mining, utilities and manufacturing operations that are being reviewed by the Air and Noise Unit of the Environmental Assessment and Approvals Branch. Other facilities that require Section 9 approval can not use this Noise Screening Process. Applications for equipment identified as candidates for the Streamline Review Unit (SRU) should not complete this process, rather they should follow specific directions from the SRU. For more information about the types of applications that may be reviewed by the SRU, please refer to the Guide to Applying for Approval (Air & Noise) dated February, 2005.

The Noise Screening Process consists of the following Steps:

- Step 1: Identify the closest Point of Reception to the facility. (Zoning Plan)
- Step 2: Determine the actual separation distance from the Point of Reception to the facility. (Scaled Area Location Plan)
- Step 3: Calculate the minimum required separation distance by completing the questionnaire on using the facility's North American Industrial Classification System Code and generic assumptions regarding the actual noise sources present at the facility.
- Step 4: Compare the actual separation distance determined in Step 2 with the minimum required separation distance calculated in Step 3 and sign the form.

The Noise Screening Process is based on the fact that the noise emissions from any noise sources at a facility will not exceed ministry noise guidelines at the closest Point of Reception provided there is a sufficient separation distance between the facility's noise sources and the Point of Reception. Using conservative assumptions regarding the likely noise sources present at a facility, a procedure was developed for calculating the minimum required separation distance to achieve compliance with the ministry noise guidelines. If the actual separation distance from the facility to the closest Point of Reception is greater than the calculated minimum required separation distance, then no further action is required. The signed Noise Screening Process form would provide sufficient supporting information for the noise assessment required by the application process.

If the closest Point of Reception is closer than the minimum required separation distance calculated in Step 3 then further assessment is required. The application may still be approved as proposed and noise control measures may not be necessary; however, a more detailed noise impact assessment using site specific information on the noise sources present at the facility must be completed. The Zoning Plan and Scaled Area Location Plan required by the Noise Screening Process will form part of the required assessment outlined in the ministry publication NPC 233 "Information to be Submitted for Approval of Stationary Sources of Sound." See the Guide to Applying for Approval (Air and Noise) dated February, 2005 for more information on the minimum required supporting information to be included with an application that is unable to pass the Noise Screening Process.

1. Applicant Information Company Name Site Name North American Industry Classification System (NAICS) Code **Treasury Metals Incorporated** Goliath Gold Project 21222 Site Address - Street information (applies to an address that has civic numbering and street information - includes Unit Identifier (identifies type of unit, such as suite & number) street number, name, type and direction) Survey Address (used for a rural location specified for a subdivided township, an unsubdivided township or unsurveyed territory) Non Address Information (includes any additional information to clarify clients' physical location) 49°45'29.39"N, 92°36'19.65"W Postal Code Municipality/Unorganized Township County/District Wabigoon Kenora 2. Noise Screening Process (please refer to the attached Noise Screening Process – Information & Instructions) Step 1 Identify Closest Point of Reception (POR) (attach Land Use Zoning Designation Plan) POR Description House - owned by Mcleish POR Acoustical Class (as per NPC-205 & NPC-232) Step 2 350 m Determine Actual Separation Distance (attach Scaled Area Location Plan) Step 3 1000 m Calculate Minimum Separation Distance (complete attached Noise Screening Process Questionnaire) Step 4 By signing this statement you are verifying that: I am the applicant or have been retained by the applicant, for the purposes of completing this Noise Screening Process; The closest Point of Reception has been identified and the Land Use Zoning Designation Plan provided by the Local Municipality is attached (Step 1); A Scaled Area Location Plan, prepared by myself, that identifies the facility, the closest Point of Reception and the actual minimum separation distance is attached (Step 2); I have accurately completed the Noise Screening Process questionnaire and identified all noise sources as required (Step 3); The actual separation distance from the facility to the closest Point of Reception, as determined in Steps 1 and 2, is greater than the minimum required separation distance determined in Step 3; and The facility belongs to one of the sectors for which the ministry has indicated the Noise Screening Process is applicable. Minimum Separation Distances – Based on Total Score (above)

Total Score	Minimum Separation Distance	Check the distance that applies
< 0 points	50 m	
< 5 points	75 m	
< 10 points	100 m	
< 20 points	200 m	
< 30 points	300 m	
< 40 points	400 m	
40 or more points	500 m	
	Distance:	m

^{*} Note: the largest minimum separation distance for Daytime Operation only in Class 1 or 2 is 300 m.

^{**} Note: the largest minimum separation distance for Evening and Daytime Operation only in Class 1 is 400 m

^{***} Note: if Adjustments for Elevated Background Noise are used then the applicant must identify the next closest receptor outside the area of influence of the roadway and show that the actual separation distance to the next closest receptor is greater than the minimum required separation distance without adjustments.

NOISE SCREENING PROCESS – INFORMATION & INSTRUCTIONS

STEP 1: IDENTIFY CLOSEST POINT OF RECEPTION

The applicant must identify and locate the closest Point of Reception (POR) affected by any noise emissions that may arise from the operations at the facility. A Point of Reception is defined as "any point on the premises of a person where sound or vibration originating from other than those premises is received".

The Point of Reception may be located on any of the following existing or zoned for future use premises:

- permanent or seasonal residences;
- hotels/motels:
- nursing/retirement homes;
- rental residences;
- hospitals;
- campgrounds; and
- noise sensitive buildings such as schools and places of worship.

For the Screening Process it is only required to identify the closest Point of Reception to the facility or any outdoor noise sources. For a more detailed assessment additional Point(s) or Reception may be required to be identified in other directions based on site specific conditions.

The closest Point of Reception must be selected using a **Land Use Zoning Designation Plan.** This plan indicates the approved local land use and nature of the neighbourhood for the area surrounding the facility. The plan must be based on up-to-date Zoning information provided by the Local Municipality. Zoning Designation Plans may be obtained from the planning department of the Local Municipality. This information may be in the form of hard copy zoning plans prepared by the municipality or electronic base maps showing local land use and features that may be available from the municipality to be printed by the applicant.

The Zoning information obtained from the Local Municipality must be detailed enough to clearly indicate the approved local land use for the individual properties surrounding the facility in a radius including the closest Point of Reception. The plan must include a scale and legend indicating the land use. The Zoning Information used to identify the closest Point of Reception must be attached to the Screening Process.

The Point of Reception Identification section should also describe the environmental noise climate at the Point of Reception in terms of the acoustical class, according to the following definitions:

- "Class 1 Area" means an area with an acoustical environment typical of a major population centre, where the background noise is dominated by the urban hum.
- "Class 2 Area" means an area with an acoustical environment that has qualities representative of both Class 1 and Class 3 Areas, and in which a low ambient sound level, normally occurring only between 23:00 and 07:00 hours in Class 1 Areas, will typically be realized as early as 19:00 hours.

Other characteristics which may indicate the presence of a Class 2 Area include:

- absence of urban hum between 19:00 and 23:00 hours;
- evening background sound level defined by natural environment and infrequent human activity; and
- no clearly audible sound from stationary sources other than from those under impact assessment.
- "Class 3 Area" means a rural area with an acoustical environment that is dominated by natural sounds having little or no road traffic, such as the following:
 - a small community with less than 1,000 population;
 - an agricultural area;
 - a rural recreational area such as a cottage or a resort area; or
 - a wilderness area.

STEP 2: DETERMINE ACTUAL SEPARATION DISTANCE

The location of the closest Point of Reception must be shown on a figure, prepared by the applicant, to determine the actual separation distance from the facility to the Point of Reception. The figure is referred to as a **Scaled Area Location Plan.**

For the Purposes of the Screening Process it may be possible to use the Zoning information provided by the Local Municipality as the Scaled Area Location Plan. However, the information is usually better presented in two separate figures because the scale of zoning plans available from the Local municipality is usually too small to sufficiently show the level of detail required by the Scaled Area Location Plan.

This figure, prepared by the applicant, must clearly indicate the location of the facility, the facility property line, all buildings on the facility and any noise sources at the facility that are located outside of the building envelope, such as dust collectors located beside a building. For the purposes of the Screening Process, it is not required to identify all noise sources, such as roof-mounted exhaust fans, on the Scaled Area Location Plan. The Scaled Area Location Plan must also show and name all local roads and features of the neighbourhood for the area surrounding the facility within a radius that includes the closest Point of Reception identified in Step 1. The figure must include a legend and scale.

The actual separation distance is calculated from the closest facility wall or outside noise source, such as a dust collector located outside the facility, to the Property Line of the selected Point of Reception. For rural receptors in Class 3 Areas, where properties may be larger and may include areas that would not be considered noise-sensitive, Points of Reception are limited to locations within 30 metres of a dwelling or a camping area, where sound or vibration originating from other than those premises is received. The location of the closest Point of Reception must be shown on the figure and the actual separation distance from the facility to the Property line of the closest Point of Reception must also be shown as a line on the figure, measured in metres.

Base maps showing the features of the surrounding neighbourhood may be obtained from the Local Municipality, Ministry of Natural Resources or other mapping companies.

The plan may include the location and features of all buildings surrounding the facility and include the topography of the surrounding area should it have an effect on the transmission of noise to a Point of Reception. However for the Screening Process this is usually not necessary. This information is required for a more detailed noise assessment.

Note: For larger facilities with outdoor noise sources, this process may have to be repeated for each outdoor noise source and different Points of Reception in order to identify the shortest actual separation distance to the closest Point of Reception.

STEP 3 – CALCULATE MINIMUM REQUIRED SEPARATION DISTANCE

Applicants are required to complete the Noise Screening Process questionnaire to calculate the minimum required separation distance that will result in compliance with the noise guidelines for the facility. Generic separation distances have been supplied that should provide a sufficient separation distance for a facility based on the type of operations conducted at the facility and the size and quantity of common noise sources associated with the type of facility under review. The minimum required distances have been provided from 1,000 m to 50 m. If a facility is closer to a Point of Reception than 50 m, you can not use this process. Conversely, if a facility is well sited, located more than 1,000m from a Point of Reception, then a detailed noise assessment is not required.

Applicants must use the North American Industry Classification System (NAICS) Code required by the application form to describe the facility. The NAICS code is determined in accordance with the Statistics Canada publication "North American Industry Classification System (NAICS) 2002 - Canada". For more information on determining the NAICS Code for a business please see www.statcan.ca. This screening process only applies to facilities with NAICS Codes starting with 21, 22, 31, 32 or 33. If the NAICS code for the facility does not fall into one of these sectors then this step of the Screening Process can not be used.

The following explanations are intended to assist with completing the Questionnaire:

Table 1.2 The presence of any one piece of equipment identified on this table should be indicated in the appropriate check box. The reference to fans and blowers is for individual large fans or blowers only. It is not required to sum the total volumetric flow rate or pressure drops across all fans or blowers at the facility. The applicant

PIBS: 4871e Last Revised: February 18, 2005 Page 8 of 9

must include any fans or blowers located on delivery trucks that supply or transport raw materials or products from the facility.

- Table 1.2 The applicant must identify large atmospheric vents that are associated with process pressure vessels, or piping such as natural gas blow down valves at pipeline compressor stations. This category of equipment is not intended to capture mandatory steam release valves from commercial boilers.
- Question 3 For each type of equipment identified on this table the total rating for all similar pieces of equipment should be summed and indicated in the appropriate question.
- Question 3(f) The applicant is required to sum the total maximum volumetric flow rate for all process or general ventilation fans or blowers at the facility that are not directly referenced elsewhere in the table. If fans are capable of operating at two speeds the higher volumetric flow rate should be used. It is not necessary to include fans associated with cooling towers or part of packaged HVAC equipment. Fans serving condensers or other cooling units should be included. The applicant must include any fans or blowers located on delivery trucks that supply or transport raw materials or products from the facility.
- Question 3(g) The applicant is required to identify if any motors powering any of the fans, blowers or air compressors are located outside the building envelope. For example if a fan serving a dust collector is located outside then the answer is yes. If the fan and dust collector are inside the building envelope the answer is no.

STEP 4: STATEMENT FACILITY MEETS SCREENING REQUIRMENTS

If an applicant can demonstrate through this screening process that the actual separation distance from the facility to the closest Point of Reception shown on the Scaled Area Location Plan is greater than the minimum required separation distance calculated in Step 3, then the person who conducted the Noise Screening Process must complete and sign off in Step 4.

PIBS: 4871e Last Revised: February 18, 2005 Page 9 of 9

APPENDIX B

Table B.1: Noise Source Data

Page 1 of 1 Treasury Metals Inc. - Goliath Gold Project, 1401701

- Wherever possible, the Source ID matches the identifiers used in the ESDM report.
- Sound Power Level of Source, in dBA, not including sound characteristic adjustments per

- Source Location: O = Outside of building, including the roof, I = Inside of building.
- Sound Characteristic, per NPC-104:
 - -S = Steady

 - Q = Quasi-Steady Impulsive

- A = Acoustic lining, plenum

- Noise control measures currently in place or specified in construction drawings: - S = Silencer/Muffler

- I = Impulsive

- B = Buzzing

- L = Lagging O = Other E = Acoustic enclosure U = Uncontrolled

- T = Tonal

- C = Cyclic

- Sound Power Level Data Source:
 Man = Manufacturer's Data
 - Mea = Measured Directly
 - Pre = Pre-tender Package

point source, and PWL is calculated from a single-vehicle passby.

Source type indicates Cadna/A modelling methodology. For Point, Line, and Area sources, PWLs represent the overall level for the entire source. Where source type is Truck Route, the source is modelled as a moving

- EC = Engineering Calc based on specifications - Same ### = same type as source no. ### - File = Measurement on File at RWDI

- B = Barrier

Where noise control measures are specified in construction drawings or were found on existing equipment, octave band sound power levels include the effects of the noise control measures. Noise control measures recommended in the mitigation section of this report are not included in this table.

Table B.2 : SOURCE LEVEL DATA AND SPL TO PWL CONVERSIONS - Version 3.4 Treasury Metals Inc. – Goliath Gold Project - 1401701

Notes to Table:

1. All measurements conducted on April 22, 2014,, using Larson Davis LD-824 SLM's / RTA's.

2. All measurements were consistent with ISO 3744:1994(E) and ISO 3746:1995 measurement standards, and the applicable portions of the MOE Publication NPC-103.

3. Calc Type of C. A, or S refer to the source geometry, and represent Cylindrical, Area, or Spherical sources, respectively.

4. SPL Ref Distance refers to the radial distance from the microphone to the acoustic centre of a spherical source or the symmetrical axis of a cylindrical source.

5. Length refers to the length of a cylindrical source or line source. A length of 1.0 m may be used to define a PWL per metre.

6. Net surface area refers to surface area corrected for partition coefficient. Partition coefficient applies only to spherical and cylindrical geometries. Sound power level is estimated using an area correction 10 log A.

7. Refer to "Spectral Weighting" column for dB or dBA application information.

Sound

Sound Power Levels in dB re. 10-12Watts:

Octave Bands	1	2	3	4	5	6	7	8	LwA
Level at Inlet	122	122	119	113	110	105	99	92	116

Estimated sound pressure level in dBA (re: 0.0002 microbar) based on a single* ducted installation:

Distance in ft	10
dBA at Inlet	99

^{*}To estimate dBA level for ducted inlet and ducted outlet (into and out of the room) type installation, deduct 20 from the LWA value shown.

Using a directivity factor of 2.

Estimated Sound Pressure based on free field, hemispherical (Q = 2) radiation at the stated distance.

Definitions:

LwA The overall (single value) fan sound power level, 'A' weighted.

dBA The environment for each fan installation influences its measured sound value, therefore dBA levels cannot

be guaranteed. Consult AMCA Publication 303 for further details.

A fan's dBA is influenced by nearby reflective surfaces.

Blower Calculation (Crocker, 2007)

Source: ML_Blwr_o

6.1 Centrifugal Blower Sound Power-Shaft Power Correlation

Realizing that acoustic efficiency (η) is sound power divided by the mechanical power that drives the source, Beranek et al. 10 developed empirical noise formulations based on shaft horsepower of the fan. The sound power radiation from a wide class of blowers (where $\eta=10^{-6}$) operating in the ducts of building ventilation systems formed the foundation of this investigation. The authors measured the sound power spectrum from 14 different blowers operating in several different systems. The overall sound power measured in these experiments correlated to

$$L_W = 90 + 10\log_{10} \text{SHP re } 10^{-12} \text{ W}$$
 (10)

where SHP is the shaft power of the blower in horsepower. The measured data for the group of fans used in this study yield a spread of about \pm 4 dB about the line computed from Eq. (10). The octave band sound power spectrum was found to slope off with increasing frequency at a rate of 5 dB per octave. The level of the first band, centered at 20 Hz, is 1 dB below the overall level predicted by Eq. (10).

Scaled Distance

Scaled distance (SD₃) = R/ $_3$ VW

where R = distance (metres) from the blast to a point of interest; and,

W = charge-weight (kilograms) detonated within any 8-millisecond delay period.

Peak Air Pressure

 $P = 37.1 \times SD_3^{-0.97}$

where P = peak air pressure (Pascals); and,

 SD_3 = scaled distance (metres per kilogram [m/kg^{1/3}]).

Peak Sound Pressure Level

dB=20 log(P/P_o)

where P_o is the reference pressure (2 x 10^{-5} Pa).

APPENDIX C

MEASUREMENT EQUIPMENT

Sound Level Meter 824 Kit 3

	Sound Level Meter			
Make and Model	Larson-Davis Model 824 SLM and RTA			
Serial No. 824A0988				
	Pre-amplifier			
Make and Model	Larson-Davis Model PRM902			
Serial No.	1462			
	Microphone			
Make and Model	Larson-Davis Model 2559 precision air-condenser microphone			
Serial No.	2800			
	Calibrator			
Make and Model	Larson-Davis CAL200 precision acoustic calibrator (1000 Hz)			
Serial No.	2570

Past 24 Hour Conditions

°C | °F Table | Graph

This table is a summary of hourly weather conditions for the past 24 hours. This summary includes the following parameters: temperature, humidity, dew point, wind speed and direction, air pressure, visibility and/or wind chill and humidex.

Date / Time (CDT)	Conditions	Temp (°C)	Humidity (%)	Dew Point (°C)	Wind (km/h)	Pressure (kPa)	Vis (km)	Wind Chill
	'		23	April 2014				
5:00	N/A	0	64	-6	SSE 11	102.1	16	*

^{*} Value not significant.

APPENDIX D

Table D.1: Key Parameters Included in the Cadna/A Noise Modelling Treasury Metals Inc. – Goliath Gold Project, 1401701

Parameter	Value	Rationale
Ground Absorption 0.8		Accounts for mostly soft (e.g., loose dirt, grass) surfaces between facility and receptors of interest
Temperature	10 °C	Ontario standard conditions
Relative Humidity	70%	Ontario standard conditions
Max. Order of Reflection	0	No significant reflections from buildings on site

Cadna/A ISO-9613 Calculation Protocol - Definitions

Parameter	Unit	Definition
-----------	------	------------

Х	(m)	X-axis Cartesian coordinate
Y	(m)	Y-axis Cartesian coordinate
z	(m)	Z-axis Cartesian coordinate
Refl.	order	Order of reflection
Freq.	(Hz)	1/1-Octave Frequency Band Centre Frequency
LxT	(dBA)	Daytime Sound Power Level
LxN	(dBA)	Night-time Sound Power Level
K0	(dB)	D_omega in ISO-9613 (correction for radiation into solid angles less than 4 Pi)
Dc	(dB)	Attenuation due to Directivity Effects
Adiv	(dB)	Attenuation Due to Divergence
Aatm	(dB)	Atmospheric Attenuation
Agr	(dB)	Ground Attenuation
Afol	(dB)	Attenuation due to foliage
Ahous	(dB)	Attenuation from houses
Abar	(dB)	Barrier Attenuation
Cmet	(dB)	Meteorological Correction
RL	(dB)	Reflection Loss
LrT	(dBA)	Resulting Daytime Noise Impacts at the receptor - Leq(1hr)
LrN	(dBA)	Resulting Night-time Noise Impacts at the receptor - Leq(1hr)

Configuration	
Parameter	Value
General

EXECUTIVE SUMMARY

Treasury Metals Inc. retained RWDI AIR Inc. (RWDI) to complete an environmental noise assessment in support of the Goliath Gold Project (the Project). The Project is a proposed gold mine near Wabigoon, Ontario. This report assesses anticipated noise emissions from the mine against the applicable criteria.

As a federal Environmental Assessment, noise guidelines developed by Health Canada for Environmental Assessments are applicable. As a development in the province of Ontario, the Ministry of Environment and Climate Change noise criteria are also applicable.

Modelling inputs include source type and locations, and sound levels. Source types and locations were taken from information provided in the Goliath Gold project description, and from Treasury Metals personnel. Sound levels were taken from information on file at RWDI, or were calculated based on equipment specifications. At this early stage of development, information can be limited therefore, where necessary, modelling has been conducted using sound levels for typical sources at a mine.

Noise sensitive receptors identified in the area are houses (seasonal or otherwise). Fourty-four individual receptors were identified. Noise modelling software was used to predict the effects of the Project at the nearest receptors, representing the worst case (loudest) impacts.

In some circumstances, sound levels of specific sources were found to cause noncompliance at noise sensitive receptors. Quieter than average equipment will be required for some pieces to achieve compliance. This equipment is commercially available. Treasury Metals has committed to ensuring that sound levels from these pieces of equipment meet these requirements.

Based on the commitment described above to limit sound levels of certain equipment, the Goliath Gold Project is predicted to be in compliance with both the Health Canada and Ministry of Environment and Climate Change guidelines at all receptors.

1. INTRODUCTION

1.1 Overview

Treasury Metals Incorporated (Treasury) has been exploring and developing the Thunder Lake Gold deposit known as the Goliath Gold Project (the Project), located near Dryden, Ontario. The Project involves the construction, operation, closure, and reclamation of a 4.5 million tonne-per-annum (Mt/a) open pit and underground mine that will operate for 12 years. This report focuses on the environmental noise emissions over the life of the project, and is intended to support the federal Environmental Assessment process.

1.1.1 Noise Considerations

The Project is located in a rural area of Northern Ontario and is not near any existing sources of industrial noise. The Goliath Gold Project will add new sources of noise to the area. Noise has the potential to affect wildlife species and human receptors in the nearby environment. This assessment addresses human impacts, and provides a quantitative evaluation of noise effects which can be used to understand the magnitude of effects on wildlife species in the vicinity of the project.

This report identifies the existing noise environment in the project area and describes the potential impacts of the Project. The potential effects associated with the development of the mine were evaluated and compared to both the Health Canada and Ministry of the Environment and Climate Change guidelines (HC, 2011 and MOE, 2013).

This assessment concentrates on comparisons with guideline limits and impacts on human receptors. The effects of potential noise and vibration impacts on other biophysical components, including wildlife, vegetation and human health are addressed separately by the appropriate disciplines.

1.1.2 Regional Setting

The Project is located in northwestern Ontario, approximately 125 kilometers (km) east of the City of Kenora, 20 km east of the City of Dryden and 325 km northwest of the City of Thunder Bay. The total area of the Project is 4,991 hectares (50 km2) covering portions of Hartman and Zealand townships east of the city of Dryden, Ontario. The Project is located approximately 3 km north of the Trans-Canada Highway, and is accessible by road.

1.1.2.1 Local Study Area

The Local Study Area was selected to represent areas where noise impacts associated with the project are likely to occur. In practice, noise impacts from a project of this magnitude are anticipated to be negligible at distances 1.5 km and greater from the nearest active project area. The study therefore focuses on areas within 1.5 km of the main features of the mine; namely the open pit mine, mill, vent raises, stockpiles, and haul truck routes.

2. VALUED COMPONENTS

2.1 Selected Valued Components and Indicators

High levels of environmental noise can affect people by impairing their enjoyment of using the land. High noise levels can also affect wildlife, causing changes in behaviour or avoidance of affected areas, for at least temporary periods of time. Environmental sound levels are therefore a Valued Component (VC) selected for study.

Table 1: Valued Components

VC	Reason for Selection of VC	Indicator
Environmental sound levels	Minimize effects on human dwellings within the region Minimize disturbance of natural terrestrial wildlife use patterns in the region	A-Weighted Sound Levels (L _{EQ} dBA) Increase in Percent Highly Annoyed as a result of changing sound levels

2.1.1 Noise Metrics & Magnitude of Effects

Environmental sound levels vary continuously over time. To account for both daily and short-term variations in sound levels, several single numerical descriptors have been developed based on large-scale psycho-acoustic studies of annoyance with environmental noise. These allow sound monitoring to be conducted for a constantly varying sound environment over an extended period, with the results described as a single number that accurately describes the environment. Terms relating to environmental noise are defined in Appendix A.

The single number descriptor commonly used in most international standards for environmental sound measurements is the energy equivalent sound level (L_{EQ}). The L_{EQ} value, expressed in dBA, is the energy-averaged, A-weighted sound level for the complete measurement interval. It is the steady, continuous sound level over a given period that has the same acoustic energy as the actual varying sound levels occurring over the same period in the measured environment. The L_{EQ} is one of the most common and useful predictors of human response to noise, and is the noise descriptor that is used in the majority of environmental noise criteria. The A-weighting accounts for the frequency content of the measured sound based on a frequency response similar to that heard by the human ear.

Another single metric descriptor which inherently accounts for additional noise sensitivity during nighttime hours is the DNL or L_{DN} . The L_{DN} is a 24-hour L_{EQ} , where 10 dB is added (arithmetically) to the nighttime sound levels during the hours of 2200h to 0700h.

The L_{EQ} can be used to calculate another metric known as Percent Highly Annoyed. High annoyance is a widely accepted indicator of human health effects resulting from exposure to environmental noise. Of particular interest is the change in Percent Highly Annoyed resulting from increases in environmental noise from The Project. There is a non-linear relationship between Percent Highly Annoyed and L_{EQ} . As a result, a project in a relatively quiet environment will not increase the Percent Highly Annoyed as much as the same project in a relatively noisy environment.

The descriptors specific to this study are:

- the 15-hour A-weighted energy equivalent sound level, L_D or L_{EQ} (day, 15), referred to as the daytime sound level;
- the 9-hour A-weighted energy equivalent sound level, L_N or L_{EQ} (night, 9), referred to as the nighttime sound level;
- the 1-hour A-weighted energy equivalent sound level, L_{EQ} (1), referred to as the hourly sound level
- the 24-hour time-weighted energy equivalent sound level, DNL or L_{DN;} and
- the change in Percent Highly Annoyed.

For reference, ranges of typical sound levels are presented in Table 2.

Table 2: Typical Sound Levels of Common Noise Sources

		els of Common Noise Sources
Sound Level	dBA	Common Noise Sources
	120	Threshold of pain
Deafening	115	Maximum noise level at a hard rock concert
Deafe	110	Accelerating motorcycle at 1 m
	105	Loud auto horn at 3 m
	100	Dance club; Maximum human vocal output at 1 m
Ponc	95	Jackhammer at 15 m
Very Loud	90	Inside a noisy factory
	85	Heavy truck pass-by at 15 m
	80	School cafeteria; Noisy bar
pn	75	Near edge of major highway; Inside automobile travelling at 60 km/h
Pnoq	70	Vacuum cleaner at 1.5 m
	65	Normal human speech, i.e., an un-raised voice, at 1 m
	60	Typical background noise levels in a large department store; Hair dryer
ate	55	Running tap water
Moderate	50	Clothes dryer; Air conditioner
≥	45	Typical background noise level in an office caused by HVAC; Flowing stream; MOECC guideline for daytime & evening noise in a rural setting
	40	Typical background noise level in a library; MOECC guideline for nighttime noise in a rural setting
Faint	35	Average whisper; Typical quiet outdoors
Ľ.	30	Broadcast studio
	25	
	20	Deep woods on a calm day
<u>i</u>	15	
Very Faint	10	
Ver	5	Human breathing
	0	Threshold of hearing, i.e., quietest sound that can be heard

2.1.2 Duration & Reversibility

Noise is temporary in nature, and stops when the source ceases to exist. Noise itself has no long-term presence and the acoustic environment will revert to a natural state with no intervention required.

2.1.3 Direction

Noise sources are directional in nature, and the directivity of a source is accounted for where appropriate in modelling. Overall, there is minimal directivity effect from the entire site due to the large number of noise sources which will collectively emit noise in all directions.

2.1.4 Frequency and Timing

Noise will be emitted throughout the life of the project, when any activities take place. Noise is therefore considered to be frequent, and continuous.

3. STUDY METHODOLOGY

3.1 Baseline Study

A baseline study was conducted in the winter of 2011 and the summer of 2013. Three sites were monitored in 2013 and one site in 2011. Further details are provided in section 5. Data from the baseline study is used to determine the appropriate sound level limits resulting from the existing natural environment sound levels.

3.2 Data Collection

Best-available data regarding future construction, operations, and decommissioning were collected from Treasury Metals, and used to predict sound levels for the Project. The basis for model inputs was primarily obtained from the project description (Treasury, 2012). Further information was gathered from Treasury through from May, June, and July 2014. Equipment sizes for sources such as the excavators and bulldozers have not yet been defined. Therefore, sizes were estimated from production levels and sound levels were predicted using numerical modelling techniques, or taken from manufacturer data for typical equipment. Where limited data was available on equipment, typical levels were selected from the RWDI library.

3.3 Modelling

3.3.1 Continuous Sources (ISO-9316)

Modelling of sound level propagation for continuous sources to the receptors was conducted using Cadna/A, a commercially available implementation of the ISO 9613 (ISO, 1994b and ISO, 1996) algorithms. Cadna/A is produced by Datakustik GmbH. The modelling took into account the following factors:

Source sound power level and directivity;

- Distance attenuation;
- Source-receptor geometry including heights, elevations and topography;
- Barrier effects of the site and surrounding buildings;
- Duration of events;
- Ground and air (atmospheric) attenuation; and
- Meteorological effects on sound propagation.

The ISO-9613 algorithms are the current international standard for airborne sound propagation, and are widely used in noise impact assessments in Ontario and Canadian jurisdictions. Modelling parameters have been selected to conform to the preferred parameters of the Ministry of Environment and Climate Change (MOECC). These parameters introduce some additional conservatism to the modelling beyond that which would be achieved with strict conformance to the ISO standard, meaning that sound levels are predicted to be slightly higher than they otherwise would be. Parameters used in the modelling are presented in Table 3.

Table 3: Parameters Used in ISO-9613 Modelling

Parameter	Model Settings	Description/Notes					
Calculation Standard	ISO-9613	All sources and attenuators are treated as					
Calculation Standard	100-9019	required by the cited standard					
Source Directivity	Directivities applied	Applied to stationary sources with significant

		downwind					
		Terrain in the area is modelled at 10 m					
Terrain	Terrain applied	resolution to account for any natural barriers					
		within the noise study area					
Reflections	0	No significant reflections from buildings on site					

3.3.2 Blasting

Modelling of blasting sound levels was conducted using numerical modelling techniques presented in the International Society of Explosives Engineers Blaster's Handbook (ISEE, 2011). Airborne vibration due to blasting activities attenuates from a site at a slower rate than ground vibrations. The distribution of this air vibration energy from a blast is also strongly influenced by the prevailing weather conditions during the blast. Other factors influencing airborne vibration propagation include:

- charge-weight per delay;
- depth of burial;
- volume of displaced rock;
- delay time intervals;
- type of explosive;
- atmospheric conditions; and,
- topography.

Further definition of these terms is provided in Appendix A.

The rate at which blast noise decays or attenuates from a blast site is dependent upon the scaled distance as follows:

- scaled distance (SD₃) = R/ $_3\sqrt{W}$
 - o where R = distance (metres) from the blast to a point of interest; and,
 - W = charge-weight (kilograms) detonated within any 8-millisecond delay period.

Prediction of maximum blast noise was based on the following equation which assumes average burial of the explosive:

- $P = 37.1 \times SD_3^{-0.97}$
 - o where P = peak air pressure (Pascals); and,
 - SD_3 = scaled distance (metres per kilogram [m/kg^{1/3}]).

This equation produces a pressure in pascals, which is then converted to decibels (dB) as shown in the following equation:

- $dB=20 \log(P/P_o)$
 - o where P_o is the reference pressure (2 x 10⁻⁵ Pa).

3.4 **Evaluation of Impacts**

The effects of the Project are ultimately evaluated by comparing modelled results to the applicable guidelines. In this study, the following comparisons will be made:

- Hourly L_{EQ} vales to MOECC criteria;
- Blasting sound levels to MOECC criteria; and
- Change in Percent Highly Annoyed to Health Canada criteria.

4. ASSESSMENT CRITERIA

The federal assessment criteria for the Project are outlined by Health Canada (HC, 2011). As the Project falls within Ontario provincial jurisdiction, and thus the MOECC guideline NPC-300 (MOE, 2013) will also be used. The HC and MOECC guidelines both focus on reducing environmental impacts as result of new developments. The HC guidelines further address the potential human health impacts associated with elevated noise levels. The specific criteria are discussed in the following sections.

4.1 Ministry of Environment and Climate Change Guidelines

Note that the Ministry of Environment changed its name in the summer of 2014 to the Ministry of Environment and Climate Change. There may be apparent inconsistency between the use of acronyms "MOE" and "MOECC" in this report, however, the use of the acronym MOECC refers to the current ministry, while the acronym MOE is used only when referring to publications by the former Ministry of Environment.

4.1.1 Continuous Sources

The MOECC guidance for continuous noise sources comes from several documents in the Noise Pollution Control or NPC series of publications. NPC-300 is referenced frequently in this section, as it presents receptor criteria and limits, and references many of the other documents in the NPC series.

4.1.1.1 Points of Reception

Sound levels from sources at the Project are required to be assessed at receptors located on noise-sensitive land uses. Noise-sensitive land uses are defined in the MOECC's environmental noise guideline, Publication NPC-300, as the property of a person that accommodates a dwelling, a noise-sensitive commercial building or a noise-sensitive institutional building. Vacant lots are considered noise-sensitive, provided they are zoned to allow a sensitive use and are accessible by road. A noise-sensitive land use may have one or more receptors.

Residential receptors include houses, cottages, and the like, whether continuously occupied or seasonal. For existing residential properties, sound levels are assessed at the façade of the building at a height of 4.5 m above local grade and an outdoor POR at a height of 1.5 m. The point of assessment for the outdoor receptors is a point 30 m from the building façade, or the property line in cases where the 30 m setback would exceed the size of the property.

Commercial and institutional receptors include hotels, churches, daycares, schools, clinics, and the like. The point of assessment for these types of receptors is at the façade of the building only; Outdoor receptors are not assessed for commercial and institutional noise-sensitive land uses.

Properties that are zoned to permit a noise-sensitive land use but are currently vacant need to be assessed as if a noise-sensitive land use exists at that location. For these noise sensitive areas, the receptors are typically considered in a location consistent with typical local building patterns, at a height of 4.5 m above local grade. In the case of unincorporated land without a minister's zoning order, the land is

generally understood to allow noise-sensitive uses, and would be assessed in the same way as land that is zoned for a noise sensitive use.

Forty-four individual noise-sensitive receptors were identified within the local study area. Where the surface mining rights have been secured by Treasury Metals, land use was assumed to be non-noise-sensitive and no receptors were identified. All other vacant lands in the vicinity of the Project that were found to be inaccessible (except by a rough cut-in through the forest) were not considered as receptors. Forty-two of the receptors were identified as houses. One was identified as the campground at Aaron Provincial Park. One receptor is a trailer located on otherwise vacant land. There are no receptors identified within the local study area to the north east, because Treasury Metals has surface rights to all land in that direction.

Since noise impacts decrease with distance from the source, the nearest receptors to the Project are considered the worst-case, and are evaluated explicitly. Other receptors are not evaluated explicitly, but effects can be seen noise contour maps. Locations of all identified receptors are presented in Figure 1. Only receptors that are explicitly evaluated are presented with labels in Figure 1.

Figure 1: Noise Sensitive Receptor Locations

4.1.1.2 Evaluation Criteria

The applicable guideline limits for the receptors in the vicinity of the Project are the "Stationary Source" guidelines for Class 3 area, set out in MOE Publication NPC-300. These guidelines state that one-hour sound exposures (A-Weighted hourly L_{EQ} values) from stationary sources in Class 3 area shall not exceed that of the background, where the background is defined as the sound level present in the environment produced by sources other than those associated with the project under assessment. The MOE Publication NPC-300 minimum sound level limits at the façade (or plane of window) are summarized as follows:

- The higher of 45 dBA or background sound, during the daytime hours (0700-1900h);
- The higher of 40 dBA or background sound, during the evening hours (1900-2300h); and
- The higher of 40 dBA or background sound, during the night-time hours (2300-0700h).

The MOE Publication NPC-300 sound level limits at an outdoor POR are applicable during the daytime and evening hours only. These limits are summarized as follows:

- The higher of 45 dBA or background sound, during the daytime hours (0700-1900h); and
- The higher of 40 dBA or background sound, during the evening hours (1900-2300h).

The applicable criterion is the higher of the background sound level and the default minimum sound level limit. Measured background sound levels, as shown in section 5, are below the minimum sound level limits. The minimum sound level limits are therefore applicable.

Operation of emergency equipment, such as generators, is not considered except during planned testing. Sound levels of planned testing of emergency equipment are evaluated separately from all other noise from the Project. In the case where multiple pieces of emergency equipment are tested together, their combined impact is evaluated against the limit. The limits for emergency equipment testing are 5 dB above the limits for other stationary sources discussed above.

4.1.1.3 Sound Quality Adjustments

Sources that have characteristics considered to be particularly annoying receive additional consideration in accordance with MOE publication NPC-104 (MOE, 1978). These guidelines specify that a penalty is applicable for tonal, cyclically varying, or quasi-steady impulsive sound characteristics. The adjustment is based on assessment at the receptor, as described in MOE Publication NPC-103 (MOE, 1978). No sources were identified to exhibit annoying sound emissions.

4.1.2 Blasting

Blasting is evaluated separately under MOECC guidelines. Guidance for noise from blasting is taken mainly from two publications, NPC-119 (MOE, 1977) and Guidelines on Information Required for the Assessment of Blasting Noise and Vibration (MOE, 1985).

4.1.2.1 Points of Reception

The receptors for assessment of blasting noise are the same as for continuous noise, as described in section 4.1.1.1.

4.1.2.2 Evaluation Criteria

Blasting activities are identified as a source for sound due to airborne vibration (concussion). The level of sound experienced at a receptor is assessed using the Peak Pressure Level measured in linear (un-weighted) decibels (dB). MOE publication NPC-119 introduces two limits, the cautionary limit, and the peek pressure level limit. The cautionary limit is 120 dB and can be applied in cases where there is no monitoring of sound levels from blasting. The peek pressure limit is 128 dB, and can only be used when sound level monitoring is conducted during blasting. The cautionary limit is used as the criteria for airborne blast noise for the Project.

4.2 Health Canada Noise Guidelines

4.2.1 Continuous Sources

The applicable federal criteria for this assessment were developed by Health Canada, and presented in Guidance for Evaluating Human Health Impacts in Environmental Assessment: Noise (HC, 2011). These guidelines are specifically intended for use in federal Environmental Assessments.

4.2.1.1 Points of Reception

The Health Canada guidelines do not provide specific guidance with respect to choosing noise sensitive receptor locations. It is clear throughout the document that it is intended for the assessment of noise as it relates to human health, therefore receptor locations should be those occupied by humans. In the absence of further guidance, the MOECC definition of a noise sensitive receptor is used in this assessment, meaning that the receptor locations for both MOECC assessment and HC assessment are the same.

4.2.1.2 Evaluation Criteria

Sound levels at receptors are evaluated against the baseline noise level in the area. The assessment method utilizes the change in Percent Highly Annoyed metric, which aims to predict change in the proportion of people that would be highly annoyed due to the elevated noise levels. The change in Percent Highly Annoyed is influenced by the absolute level of the sound experienced at the receptor. There is a non-linear relationship between Percent Highly Annoyed and L_{EQ} . In practice this means that in a quiet area, an increase in sound level will result in a lower change in percent highly annoyed than the same change in sound level in a louder area. Since The Project is in a relatively quiet area, the change in Percent Highly Annoyed would typically be expected to be low. The practical result of this is that the MOECC assessment criteria discussed in section 4.1 are the more stringent of the two guidelines.

The Health Canada noise assessment criteria are as follows:

Maximum L_{DN} of 75 dBA

Maximum Allowed Increase in Percent Highly Annoyed of 6.5%

The Health Canada guidelines require that all baseline noise assessments and project-related noise emissions be evaluated in terms of the L_{DN} which accounts for full day exposures.

The guidelines apply to the construction, operational, and closure phases of the project. The inclusion of the construction and closure phases is required as those phases of the project will be longer than one year in duration.

4.2.2 Blasting

Blasting is considered a "High Energy Impulse" under the Health Canada noise guidelines. The guidelines dictate that the assessment of impulsive noise is to be combined with the assessment of steady state noise. A 12 dB penalty is added to the high energy impulsive component of the combined total.

5. BASELINE STUDIES

A baseline study was conducted in the winter of 2011 and the summer of 2013. Three sites were monitored in 2013 and one site in 2011. Further details are provided in section 5. Data from the baseline study is used to determine the appropriate sound level limits resulting from the sound levels in the existing natural environment.

The more detailed baseline assessment completed in 2013, was used as the basis for this project, and is documented in detail the Baseline Noise Assessment Report (RWDI, 2013). The baseline study did not present the L_D , L_N , or L_{DN} levels. These have been calculated from the raw data and are presented in this section along with the original baseline data. Key items from that report are summarized in this section.

5.1 Baseline Monitoring Locations

Long-term measurements of background ambient sound levels at one location were conducted from December 5 to December 7, 2011, near the project site as shown in Figure 2.

Figure 2: Baseline Monitoring Locations, Winter 2011

Additional monitoring at three representative locations to the west of the site was conducted from July 3 to July 9, 2013. The locations of baseline monitoring stations are shown in Figure 3.

Figure 3: Baseline Monitoring Locations, Summer 2013

5.2 Noise Environment

The study area is in a rural location outside a small northern community with low levels of human activity. Noise observed during the study consisted of mostly wind, small animals, bird noise and noise from the TransCanada Highway which runs in near proximity to the study area.

Background ambient sound levels in remote areas are typically low, ranging from about 25 to 40 dBA. These values are similar to those measured for the Project. At these levels, noise would be described as faint.

Table 4: Baseline Study Results

Location	Lo	owest Hourly (dBA)	L _{EQ}	L _D (Day, 15h)	L _N (Night, 9h)	L _{DN}	
	Daytime ^[1]	Evening ^[1]	Nighttime ^[1]	(dBA)	(dBA)	(dBA)	
Site 1	39	38	35	49	46	48	
Site 2	38	37	32	44	43	44	
Site 3	32	35	28	45	41	44	
Site 4 [2]	28	34	30	-	-	-	

Notes:

- 1. Daytime refers to 0700-1900h; Evening refers to 1900-2300h; and
 - Nighttime refers to 2300-0700h.
- 2. The LD and LN, and LDN have not been calculated for the 2011 field program, as the monitoring location is not representative of receptor locations.

5.2.1 **Temporal Variation**

The difference between daytime and nighttime sound levels were generally small, and are attributed mainly to very low level of noise from human activity which could not be screened out.

5.3 **Applicability**

The measured ambient sound levels will be used in the Percent Highly Annoyed analysis, and the determination of background levels for evaluation in the MOECC guidelines.

The measurement sites that are of most interest are those which most closely represent the sound levels at the noise sensitive receptors. Of the four measurements, the measurement at Site 2 is most representative of the acoustical environment of the noise sensitive receptors. The sound environment at site 1 is mainly dominated by noise from the Trans-Canada Highway, whereas site 3 has very little influence from the highway both of which are not representative for the worst case receptors assessed. Site 2 data will be used in the assessment for all receptors.

CONSTRUCTION AND SITE PREPARATION PHASE 6.

6.1 **Description of Continuous Operations**

Construction and Site Preparation phases will include tree clearing, grubbing, stripping of overburden, crushing of aggregate for road construction, blasting, and construction of project facilities. Many of these activities have the potential for local noise impacts. The duration of the Site Preparation and the Construction phase is estimated to be 3 years. HC guidelines suggest that for construction operation with durations greater than 1 year, noise should be assessed in the same way as operational noise, and thus entailing quantitative assessment. It is conservatively assumed in the assessment of Construction and Site Preparation that these activities would occur 24-hours per day, with no change in the nature of the operations during daytime, evening, or nighttime.

6.2 Noise Source Summary

6.2.1 Continuous Sources

For the most part, details regarding specific equipment to be used during the Construction and Site Preparation Phase were not yet available at the time of this assessment. It was assumed that, where possible, Treasury Metals would attempt to secure heavy equipment that would later be used in the Operations Phase. The heavy equipment modelled for the Construction and Site Preparation phase is therefore a subset of the equipment that was modelled for the operations phase, with a portable rock crusher added as an additional piece of equipment. Table 5 shows the sources that were modelled in this phase, including quantity of each type of source, and respective sound power levels.

Table 5: Modelled Noise Sources for the Construction and Site Preparation Phase

Equipment	Otv	Octave Band Sound Power Level (dB)								Overall	
Equipment	Qty	31.5	63	125	250	500	1000	2000	4000	8000	dBA
Drill	1	101	96	103	103	100	102	101	97	89	107
Excavator	1	95	118	110	100	97	93	94	90	85	101
Haul Truck	6	100	96	102	104	103	103	102	95	90	107
Bulldozer	2	96	96	101	94	95	95	94	88	79	100
Front end loader	1	98	97	105	102	97	94	91	88	82	100
Dewatering Pump	1	78	79	80	82	83	85	83	79	72	89
Portable Crusher	1	113	122	116	108	109	107	105	103	99	113

Sound power levels for all mobile equipment were obtained from representative sound power data on file. The sound power level for the dewatering pump was calculated based on typical specifications.

During the construction phase, work is expected to progress simultaneously across most areas of the site. To account for this, the modelling approach used was to average the cumulative sound power level of all Construction and Site Preparation sources across the entire site area. This accounts for the very mobile nature of the sources, and provides a good indication of average sound levels in the absence of a detailed construction plan. Figure 4 shows the location of the area source used for the prediction of sound levels from this phase.

Figure 4: Source Locations, Construction and Site Preparation Phase

6.2.2 **Blasting**

Blasting during the Construction and Site Preparation phase is expected to take place once per day in the area of the open pit mine during construction. Sound levels from blasting were calculated as described in section 3.3.2.

In order to accurately assess sound levels from blasting, the blast is assumed to happen at the edge of the pit closest to each receptor. That is, for each receptor location, the worst-case blast location is chosen.

At the time of the assessment, limited details regarding the expected blast configurations were available, therefore the modelling assumed a maximum charge per delay of 100 kg.

Predicted Sound Levels 6.3

Sound contours (isopleths of equal sound level) resulting from the Construction and Site Preparation phase are presented in Figure 5. A modelling output file showing the details of a sample calculation at NR03 is included in Appendix B.

Figure 5: Predicted Sound Levels, Construction and Site Preparation Phase

6.3.1 Assessment to MOECC Guidelines

6.3.1.1 Continuous Sources

Sound levels were assessed at the five worst-case receptors as discussed in section 4.1.1.1. All levels are predicted to be in compliance with the NPC-300 (MOE, 2013) minimum sound level limits for a class 3 area. Table 6 shows the predicted sound levels and applicable limits.

Table 6: Assessment of Construction and Site Preparation Noise to MOECC Guidelines

	Receptor			Sound Level at	
ID	Description	Daytime	Evening	Nighttime	Receptor L _{EQ} (dBA)
NR03	House - owned by Mcleish	45	45	40	40
NR03_O	Outdoor receptor- Mcleish	45	40	-	39
NR04	House - owned by Nystroms	45	45	40	33
NR04_O	Outdoor receptor- Nystroms	45	40	-	32
NR30	House - East Thunder Lake Road	45	45	40	33
NR30_O	Outdoor receptor - East Thunder Lake Road	45	40	-	32
NR44	House - Near Trans-Canada Highway	45	45	40	29
NR44_O	Outdoor receptor - Near Trans- Canada Highway	45	45	-	28
NR47	House - East Thunder Lake Road	45	45	40	29
NR47_O	Outdoor receptor - East Thunder Lake Road	45	40	-	28

6.3.1.2 Blasting

Sound levels from blasting were evaluated separately from sounds due to continuous noise sources as per the guidance. Levels were assessed at the five worst-case receptors as discussed in section 4.1.1.1. A radius of influence was also determined, which is the distance from a blast where the sound levels will fall off to the precautionary limit. The radius of influence is 95 m in all directions from the blasting. Any receptor further than 95 m from a blast will therefore experience effects lower than the NPC-119 precautionary limit.

All levels at receptors are predicted to be in compliance with the NPC-300 minimum sound level limits for a class 3 area. Table 7 shows the predicted sound levels and applicable limits.

Table 7: Predicted Sound Levels from Blasting

Receptor	Distance (m)	Peak Sound Pressure Level (dB)
Cautionary Limit	95	120
NR03	1813	78
NR04	3000	71
NR30	2373	75
NR44	3734	68
NR47	3187	70

6.3.2 Assessment to Health Canada Guidelines

Change in Percent Highly Annoyed was assessed at the five worst-case receptors as discussed in section 4.1.1.1. Site 2 from the 2013 baseline study was used as the basis for the ambient noise data as it best represents the acoustic environment at all receptor locations. 10 dB penalties were applied to both the baseline and project noise levels to account for the rural nature of the site location.

The change in Percent Highly Annoyed at each receptor is predicted to be below the 6.5% threshold, and absolute sound levels are predicted to be below the 75 dBA threshold. Table 8 shows the predicted sounds levels and change in Percent Highly Annoyed.

Blasting at the site is to take place no more than once per day, during daytime hours only. Since the Health Canada guidelines average sound levels over a 24-hour period, with additional penalty for the nighttime period, a single blast per day was considered to be infrequent and was not further assessed against these guidelines.

Table 8: Assessment of Construction and Site Preparation Noise to HC Guidelines

Receptor	L _{DN} (dBA)	Change in Percent Highly Annoyed	Complies with HC Guidelines?
NR03	56	1.6	Yes
NR03_O	56	1.4	Yes
NR04	49	0.4	Yes
NR04_O	48	0.3	Yes
NR30	49	0.3	Yes
NR30_O	48	0.3	Yes
NR44	45	0.1	Yes
NR44_O	44	0.1	Yes
NR47	45	0.1	Yes
NR47_O	44	0.1	Yes

Details of the L_{DN} and Percent Highly Annoyed calculations are included in Appendix B.

6.4 Mitigation

In order to achieve compliance at all receptors, the sound power levels of equipment were limited in some cases. The limited power levels are still within the accepted range of power levels from this type of equipment from different manufacturers and of different ages, but are quieter than average. The sound power levels presented in Table 5 reflect these reduced levels. Treasury Metals has committed to ensuring that sound levels from these pieces of equipment meet these requirements.

Treasury metals will ensure that best practices are followed during the Construction and Site Preparation phase to ensure that sound levels are minimized. These best practices will include:

- Conduct heavy construction activity between the hours of 07:00 and 22:00 if possible to reduce the potential impact of construction noise;
- Advise nearby residents of significant noise-causing activities such as mine blasts and schedule these events to reduce disruption to them;
- Ensure that all internal combustion engines are fitted with appropriate muffler systems; and
- Employ controlled blasting methods such as penetrating cone fracture.

6.5 **Residual Effects**

Residual effects are those that remain when all mitigation options have been incorporated into the project design and operation. As all sound levels are predicted to comply with the applicable criteria, it is not anticipated that there will be residual effects for this site.

6.6 **Conclusions**

The results of the noise assessment for the Construction and Site Preparation Phase can be summarized as follows:

- Predicted worst case hourly noise levels range from 28 to 40 dBA at worst-case receptors;
- Predicted L_{DN} levels range from 44 to 56 dBA at worst-case receptors;
- Predicted increase in Percent Highly Annoyed range from 0.1 to 1.6 at worst-case receptors; and
- Predicted radius of influence from blasting is 95 m in all directions from the blasting site which is predicted to comply with the exclusionary limit at any receptor.

Predicted sound levels are shown to be below the guideline limits at each of the receptors for the Construction and Site Preparation phase. The Construction and Site Preparation phase is predicted to comply with the requirements of Health Canada and the MOECC guidelines.

7. OPERATIONS PHASE

The assessment of noise from the operation phase focuses on the predictable worst-case year, which includes both open pit and underground mining. Other activities that may take place during the operating life of the mine, such as remediation of the open pit, are anticipated to generate lesser noise, and are not explicitly assessed.

7.1 **Description of Continuous Operations**

The operations phases will include both underground and open face mining activities. The open face mining activities include drilling, blasting, dozing, excavating and the transportation of rock material around site. The underground activities include the operation of intake and exhaust vent raises and the transportation of rock material to the surface. Emergency power generation occurs on site and testing of emergency generators occurs only during the daytime hours. Many of these activities have the potential for local noise impacts. The duration of the operations phase is estimated to be 10 years. It is

conservatively assumed in the assessment of operations that these activities would occur 24-hours per day, with no change in the nature of the operations during daytime, evening, or nighttime, other than the generator testing.

7.2 **Noise Source Summary**

7.2.1 **Continuous Sources**

For the most part, limited details regarding types of equipment used during the operations phase were available at the time of this assessment. Sound power levels for all mobile equipment were obtained from representative sound power data on file. The sound power level for the dewatering pump and aeration tank blower were conservatively calculated based on typical specifications. The sound power level for the exhaust louvers on the mill building were calculated assuming an indoor sound power level of 85 dB within the mill facility. This is a typical objective for indoor sound levels in order to comply with occupational health and safety regulations. The calculations are based on 3.0 m/s air velocities and six air changes per hour within the building. Where appropriate, source emissions were time-weighted based on typical operating assumptions. Table 9 shows the sources that were modelled in this phase, including number each type of source, and sound power levels. Power levels shown in Table 9 do not account for time weighting.

Table 9: Modelled Noise Sources for the Operations Phase

			0	ctave E	Band S	Sound	Power	Level (d	dB)		Overall
Equipment	Qty.	31.5	63	125	250	500	1000	2000	4000	800 0	dBA
150 kW Emergency Generator	1	-	102	95	98	108	107	106	102	100	112
600 kW Emergency Generator	1	-	83	95	103	108	109	107	103	99	113
Aeration Tank Blower	1	109	104	99	94	89	84	79	74	69	91
Jaw Crusher	1	89	87	88	91	94	95	94	90	83	99
Exhaust Louver for Mill	14	-	-	-	-	64	-	-	-	-	61
Furnace Exhaust	1	-	85	85	75	70	68	63	58	53	74
Kiln Fan	1	-	95	93	93	93	90	85	79	72	94
Front End Loader	1	98	97	105	102	97	94	91	88	82	100
Rock Drop at Crusher	1	114	116	121	122	113	114	111	106	100	119
Dewatering Pump	1	90	90	92	94	96	97	95	91	84	101
Drill	2	101	96	103	103	100	102	101	97	89	107
Bulldozer	3	96	96	101	94	95	95	94	88	79	100
Hydraulic Excavator	2	95	118	110	100	97	93	94	90	85	101
Rock Drop at Stockpiles	3	100	106	116	107	109	103	104	103	103	112
Exhaust Vent Raise	2	-	117	117	114	108	105	100	94	87	111
Fresh Air Intake Vent Raise	1	-	117	117	114	108	105	100	94	87	111
50 Ton Haul Truck	14	100	96	102	104	103	103	102	95	90	107

All sources other than haul truck noise were modelled as point sources. Haul truck noise was modelling using line sources. Noise source locations were chosen to represent a predictable worst-case level of impacts. As an example of this, the majority of haul truck traffic is modelled on the longest haul route. All open pit mine sources were modelled at ground level, to represent the beginning of a new pit, or the remediation afterwards.

In the operating phase, ground contours have been modelled accounting for a 2 m high berm around the perimeter of the pit, a minimum height of 3 m at the low grade stockpile, and a minimum height of 10 m at the overburden pile.

Figure 6: Source Locations, Operations Phase

7.2.2 Blasting

Blasting during the operations phase is expected to take place once per day in the area of the open pit mine. Sound levels from blasting were calculated as described in section 3.3.2.

In order to accurately assess sound levels from blasting, the blast is assumed to happen at the edge of the pit closest to each receptor. That is, for each receptor location, the worst-case blast location is chosen.

At the time of the assessment, limited details regarding the expected blast configurations were available, therefore the modelling assumed a maximum charge per delay of 100 kg.

7.3 Predicted Sound Levels

Sound contours (isopleths of equal sound level) resulting from the Operation phase are presented in Figure 7. These contours include the effects of all continuous noise sources except for emergency generator testing. A modelling output file showing the details of a sample calculation at NR03 is included in Appendix B.

Figure 7: Predicted Sound Levels, Operations Phase

7.3.1 Assessment to MOECC Guidelines

7.3.1.1 Continuous Sources

Sound levels were assessed at the five worst-case receptors as discussed in section 4.1.1.1. All levels are predicted to be in compliance with the NPC-300 (MOE, 2013) minimum sound level limits for a class 3 area. Table 10 shows the predicted sound levels and applicable limits for continuous sources except for generator testing. Generator testing is assessed separately, and the results of that assessment are shown in Table 11.

7.3.1.2 Blasting

Sound levels from blasting were evaluated separately from sound from continuous noise sources. Levels were assessed at the five worst-case receptors as discussed in section 4.1.1.1. A radius of influence was also determined, which is the distance from a blast where the sound levels will fall off to the precautionary limit. The radius of influence is 95 m in all directions from the blasting. Any receptor further than 95 m from a blast will therefore experience effects lower than the NPC-119 precautionary limit.

All levels at receptors are predicted to be in compliance with the NPC-300 minimum sound level limits for a class 3 area. Table 12 shows the predicted sound levels and applicable limits.

Table 12: Predicted Sound Levels from Blasting

Receptor	Distance (m)	Peak Sound Pressure Level (dB)
Cautionary Limit	95	120
NR03	1813	78
NR04	3000	71
NR30	2373	75
NR44	3734	68
NR47	3187	70

7.3.2 Assessment to Health Canada Guidelines

Change in Percent Highly Annoyed was assessed at the five worst-case receptors as discussed in section 4.1.1.1. Site 2 from the 2013 baseline study was used as the basis for the ambient noise data as it best represents the acoustic environment at all receptor locations. 10 dB penalties were applied to both the baseline and project noise levels to account for the rural nature of the site location.

The change in Percent Highly Annoyed at each receptor is predicted to be below the 6.5% threshold, and absolute sound levels are predicted to be below the 75 dBA threshold. Table 9 shows the predicted sounds levels and change in Percent Highly Annoyed.

Blasting at the site is to take place no more than once per day, during daytime hours only. Since the Health Canada guidelines average sound levels over a 24-hour period, with additional penalty for the nighttime period, a single blast per day was considered to be infrequent and was not further assessed against these guidelines.

Table 13: Assessment of Operating Noise to HC Guidelines

Receptor	L _{DN} (dBA)	Change in Percent Highly Annoyed	Complies with HC Guidelines?
NR03	57	1.8	Yes
NR03_O	55	1.4	Yes
NR04	51	0.5	Yes
NR04_O	50	0.4	Yes
NR30	50	0.4	Yes
NR30_O	50	0.4	Yes
NR44	47	0.2	Yes
NR44_O	46	0.2	Yes
NR47	47	0.2	Yes
NR47_O	46	0.2	Yes

Details of the L_{DN} and Percent Highly Annoyed calculations are included in Appendix B.

7.4 Mitigation

In order to achieve compliance at all receptors, the sound power levels of equipment were limited in some cases. The limited power levels are still within the accepted range of power levels from these types of equipment from different manufacturers and of different ages, but are quieter than average. The sound power levels presented in Table 9 reflect these reduced levels. Treasury Metals has committed to ensuring that sound levels from these pieces of equipment meet these requirements.

Treasury metals will ensure that best practices are followed during the Operations phase to ensure that sound levels are minimized. These best practices will include:

- Conduct heavy construction activity between the hours of 07:00 and 22:00 if possible to reduce the potential impact of construction noise;
- Advise nearby residents of significant noise-causing activities such as mine blasts and schedule these events to reduce disruption to them;
- Ensure that all internal combustion engines are fitted with appropriate muffler systems; and
- Employ controlled blasting methods such as penetrating cone fracture.

7.5 Residual Effects

Residual effects are those that remain when all mitigation options have been incorporated into the project design and operation. As all sound levels are predicted to comply with the applicable criteria, it is not anticipated that there will be residual effects for this site.

7.6 Conclusions

The results of the noise assessment for the operations phase can be summarized as follows:

- Predicted worst case hourly noise levels range from 30 to 40 dBA at worst-case receptors; and
- Predicted worst case hourly noise levels during generator testing range from 25 to 43 dBA at worstcase receptors; and
- Predicted L_{DN} levels range from 46 to 57 dBA at worst-case receptors; and
- Predicted increase in Percent Highly Annoyed range from 0.2 to 1.8 at worst-case receptors.
- Predicted radius of influence from blasting is 95 m in all directions from the blasting site which is predicted to comply with the exclusionary limit at any receptor.

Predicted sound levels are shown to be below the guideline limits at each of the receptors for the operations. The operations phase is predicted to comply with the requirements of Health Canada and the MOECC guidelines.

8. CLOSURE, DECOMMISSIONING AND RESTORATION PHASE

Activities directly related to closure of mining operations on site, as well as any ongoing remediation activities are assessed together in the closure phase.

8.1 Description of Continuous Operations

Closure, Decommissioning and Restoration phases will include backfilling and flooding of the open pits and underground mine area, disassembling of infrastructure and equipment as well as overall site maintenance. Many of these activities have the potential for local noise impacts. The duration of the Closure, Decommissioning and Restoration phase is estimated to be 2 years. It is conservatively assumed in the assessment of Closure, Decommissioning and Restoration that these activities would occur 24-hours per day, with no change in the nature of the operations during daytime, evening, and nighttime. No blasting would take place during this phase.

8.2 Noise Source Summary

Details regarding types of equipment used during the closure phase were not yet available at the time of this assessment. It was assumed that Treasury Metals would use the same types of equipment used in both the previous phases. The heavy equipment modelled for the Closure, Decommissioning and Restoration phase is therefore a subset of the equipment that was modelled for the operations phase. Table 14 shows the sources that were modelled in this phase, including number of sources, and sound power levels.

Table 14: Modelled Noise Sources for the Closure, Decommissioning and Restoration Phase

Equipment	Otv	Octave Band Sound Power Level (dB)							Overell		
Equipment	Qty	31.5	63	125	250	500	1000	2000	4000	8000	Overall dBA 101 107 100 100
Excavator	2	95	118	110	100	97	93	94	90	85	101
Haul Truck	6	100	96	102	104	103	103	102	95	90	107
Bulldozer	2	96	96	101	94	95	95	94	88	79	100
Front end loader	1	98	97	105	102	97	94	91	88	82	100
Dewatering Pump	1	90	90	92	94	96	97	96	91	84	102

Sound power levels for all mobile equipment were obtained from representative sound power data on file. The sound power level for the dewatering pump was calculated based on typical specifications.

During the closure phase, work is expected to progress simultaneously across most areas of the site. To account for this, the modelling approached used was to average the cumulative sound power level of all closure sources across the entire site area. This accounts for the very mobile nature of the sources, and provides a good indication of average sound levels in the absence of a detailed closure plan. Figure 8 shows the location of the area source used for the prediction of sound levels from this phase.

Figure 8: Source Locations, Decommissioning and Restoration Phase

8.3 Predicted Sound Levels

Sound contours (isopleths of equal sound level) resulting from the Closure, Decommissioning and Restoration Phase are presented in Figure 9. A modelling output file showing the details of a sample calculation at NR03 is included in Appendix B.

Figure 9: Predicted Sound Levels, Closure, Decommissioning and Restoration Phase

8.3.1 Assessment to MOECC Guidelines

Sound levels were assessed at the five worst-case receptors as discussed in section 4.1.1.1. All levels are predicted to be in compliance with the NPC-300 (MOE, 2013) minimum sound level limits for a class 3 area. Table 15 shows the predicted sound levels and applicable limits.

Table 15: Assessment of Closure, Decommissioning and Restoration Noise to MOECC Guidelines

8.3.2 Assessment to Health Canada Guidelines

Change in Percent Highly Annoyed was assessed at the five worst-case receptors as discussed in section 4.1.1.1. Site 2 from the 2013 baseline study was used as the basis for the ambient noise data as it best represents the acoustic environment at all receptor locations. 10 dB penalties were applied to both the baseline and project noise levels to account for the rural nature of the site location.

The change in Percent Highly Annoyed at each receptor is predicted to be below the 6.5% threshold, and absolute sound levels are predicted to be below the 75 dBA threshold. Table 16 shows the predicted sounds levels and change in Percent Highly Annoyed.

Table 16: Assessment of Closure, Decommissioning and Restoration Noise to HC Guidelines

Receptor	L _{DN} (dBA)	Change in Percent Highly Annoyed	Complies with HC Guidelines?
NR03	55	1.3	Yes
NR03_O	55	1.2	Yes
NR04	48	0.3	Yes
NR04_O	47	0.2	Yes
NR30	47	0.2	Yes
NR30_O	46	0.2	Yes
NR44	43	0.1	Yes
NR44_O	42	0.1	Yes
NR47	43	0.1	Yes
NR47_O	42	0.1	Yes

Details of the L_{DN} and Percent Highly Annoyed calculations are included in Appendix B.

8.4 Mitigation

In order to achieve compliance at all receptors, the sound power levels of equipment were limited in some cases. The limited power levels are still within the accepted range of power levels from these type of equipment from different manufacturers and of different ages, but are quieter than average. The sound power levels presented in Table 5 reflect these reduced levels. Treasury Metals has committed to ensuring that sound levels from these pieces of equipment meet these requirements.

Treasury metals will ensure that best practices are followed during the Closure, Decommissioning and Restoration phase to ensure that sound levels are minimized. These best practices will include:

- Conduct heavy construction activity between the hours of 07:00 and 22:00 if possible to reduce the potential impact of construction noise;
- Advise nearby residents of significant noise-causing activities and schedule these events to reduce disruption to them; and
- Ensure that all internal combustion engines are fitted with appropriate muffler systems.

8.5 Residual Effects

Residual effects are those that remain when all mitigation options have been incorporated into the project design and operation. As all sound levels are predicted to comply with the applicable criteria, it is not anticipated that there will be residual effects for this site.

8.6 Conclusions

The results of the noise assessment for the Closure, Decommissioning and Restoration phase can be summarized as follows:

- Predicted worst case hourly noise levels range from 26 to 39 dBA at worst-case receptors; and
- Predicted L_{DN} levels range from 42 to 55 dBA at worst-case receptors; and
- Predicted increase in Percent Highly Annoyed range from 0.1 to 1.3 at worst-case receptors.

Predicted sound levels are shown to be below the guideline limits at each of the receptors for the Closure, Decommissioning and Restoration phase. The Closure, Decommissioning and Restoration phase is predicted to comply with the requirements of Health Canada and the MOECC guidelines.

9. UNCERTAINTY

The modelling used in this assessment has an overall prediction accuracy that is dependent on two factors: the accuracy of the accustical source data, and the accuracy of the noise propagation model.

The sound level data used in this assessment is based on manufacturers data, engineering calculations, or data from similar equipment, and would be expected to have a high degree of accuracy. Efforts should be made when procuring equipment for the Project to verify that equipment sound levels are similar to those modelled.

The ISO 9613 propagation algorithms have a published accuracy of + 3 dBA over source-receiver distances between 100 and 1000 m. A similar degree of accuracy would be expected over the distances considered in this assessment. This is considered to be an excellent agreement for an environmental noise model over such a large distance. A 3 dBA increase or decrease would be considered imperceptible to humans.

In addition, the ISO 9613 model produces results that are representative of meteorological conditions favouring sound propagation (e.g., downwind and/or inversion conditions). These conditions do not occur all the time, and therefore, the model predictions will be conservative, and actual sound levels at the receptors may be less than indicated for much of the time.

Based on the above, the overall model prediction confidence is expected to be high.

10. MONITORING

Health Canada recommends monitoring when predicted noise levels verge upon the level where adverse human health effects can potentially occur. Since the predicted levels are well below that point, monitoring is not recommended under the Health Canada guidelines.

Monitoring and follow up studies are not required by NPC-300 (MOE, 2013), but may be requested by the MOECC as part of an Environmental Compliance Approval. Details of this monitoring would be determined in the Environmental Compliance Approval application process.

Monitoring of blasting sound levels is required only where sound levels are predicted to be above the NPC-119 precautionary limits. Since impacts are not anticipated to exceed the precautionary limits, no blast monitoring is required.

No ongoing monitoring is recommended. However, in the event that noise complaints are received during the life of the Project, it is recommended that actions are taken promptly to monitor sound levels. Sound levels must be monitored for a sufficient length of time as to determine the validity and cause of the complaint. Details of a monitoring program in the case of a complaint will be determined on case-by-case basis, as the location of the complainant and status of the Project will influence the best practices in monitoring.

11. SUMMARY AND CONCLUSIONS

A systematic approach was adopted to identify potential noise sources and quantify the emissions due to Project activities at the Goliath Gold site. Best-available data regarding future construction, operations, and decommissioning were collected from Treasury Metals, and used to predict sound levels for the Project. Sound levels from blasting were evaluated separately from sound from continuous noise sources.

This assessment concentrates on comparisons with guideline limits and impacts on human receptors. The effects of potential noise impacts on other biophysical components, including wildlife, vegetation and human health are addressed separately by the appropriate disciplines.

The results of the noise assessment for the Project can be summarized as follows:

- Predicted worst case hourly noise levels range from 26 to 40 dBA at worst-case receptors; and
- Predicted L_{DN} levels range from 42 to 57 dBA at worst-case receptors; and
- Predicted increase in Percent Highly Annoyed range from 0.1 to 1.8 at worst-case receptors.
- Predicted radius of influence from blasting is 95 m in all directions from the blasting site which is predicted to comply with the exclusionary limit at any receptor.

Predicted sound levels are shown to be below the guideline limits at each of the receptors for all phases. The Project is predicted to comply with the requirements of Health Canada guidelines (HC, 2011) and the NPC-300 (MOE, 2013) guuidelines.

RE:	Treasury Metals Inc. – Goliath G Acoustic Environment Technical Memorandum	iold Project

As part of the assessment of the sound levels associated with the Goliath Gold project (i.e., the "Project") in northwestern Ontario, several information requests were submitted by the Canadian Environmental Assessment Agency. This memorandum is provided to address the technical details in support of the responses to those information requests, specifically:

- TMI_183-AE(1)-21 ... Definition of the regional and local study areas;
- TMI_186-AE(1)-24 ... Inclusion of noise due to offsite project vehicle traffic;
- TMI_190-AE(1)-28 ... Assessment of blasting;
- TMI_191-AE(1)-29 ... Inclusion of adjustments for sound character.

This memorandum forms part of the environmental noise and vibration technical assessment contained in Appendix H of the project's revised Environmental Impact Statement (EIS).

1 STUDY AREAS

Information request TMI_183-AE(1)-21 requested a clearer definition of the regional study area (i.e., "RSA") and local study area (i.e., "LSA") in relation to noise, using quantitative factors as a rationale.

Sound and vibration from a source decay with distance. Additional factors can attenuate levels as a sound or vibration wave travels from the source to receiver, such as ground and air absorption, but distance is a primary factor that is linked to the geometrical spreading and attenuation of the wave. Ground-borne vibration attenuates at a much faster rate than sound in air, and thus any study area defined for sound would also include vibration.

Treasury Metals Inc. - Goliath Gold Project Acoustic Environment RWDI#1602163 March 12, 2018

On the above basis, most industrial sources decay to a low sound level at distances greater than 3000m from a source. For example, a source sound power level of 100 dBA (i.e., typical of the sound emission from a project of this type) conservatively results in a sound pressure level of 22 dBA at a distance of 3000m based on distance attenuation alone. Ten such sources would result in a combined sound level of 32 dBA which is still well-below typical regulatory limits of 40 dBA; in other words, ten similar projects/sources would result in a combined influence well below standard regulatory limits.

The RSA for sound can thus be defined as a 3000m setback from the nearest active project area, with sources beyond this range not contributing significantly to total sound levels as noted above. This buffer was reviewed for major sources of stationary sound unrelated to the project that could contribute to total sound. No sources were identified; hence, no combined effects from other sources were considered.

The LSA was defined within the RSA for detailed acoustic assessment based on a setback of 1500m (i.e., see blue line Figure 1). At this setback distance, sound sources such as those given in the above example would result in sound levels on the order of 28 dBA. These levels could reasonably begin to influence the local background conditions in a rural area which are commonly in the 30-35 dBA range. This distance also aligns to the valid range of most sound propagation algorithms used in detailed assessment, including the ISO 9613-2 "Attenuation of Sound During Propagation Outdoors" algorithm used in this assessment, which also reflects industry-standard practice.

Key sensitive receptors were identified within the LSA in each cardinal compass direction from the nearest active project area for the detailed acoustic assessment. These receptors would represent the limiting case for sound as receptors located further away would experience lower sound levels (i.e., based on the principle of geometric spreading). A total of 42 noise-sensitive receptors were identified. As no receptors were identified to the north of the project, the region of acoustical focus that includes all of these receptors (i.e., an "acoustic study area", see red line in Figure 1) extends in a rectangular area approximately 500m away from the mine site at its nearest point to the north (i.e., sound levels of 39 dBA near inaccessible vacant lands) and approximately 2500m to the southwest at its furthest point (i.e., sound levels of 24 dBA).

Figure 1: Outline of Local Study Area (blue) and Acoustic Study Area (red)

2 OFFSITE VEHICLE TRAFFIC

Information request TMI_186-AE(1)-24 requested that offsite vehicle traffic be quantitatively considered in the environmental noise assessment. The noise from vehicle traffic to and from the Project site (i.e., offsite traffic) during the operation of the Project was considered to be minor, but has been assessed quantitatively as requested.

Access to and from the site will be from Highway 17, along Anderson Road, and then along Nursery Road. There are three worst-case sensitive receptors along this route that would be most affected by changes in the local traffic for noise; these are receptors NR03, NR04, and NR44 as shown in Figure 1 (and also in Figure 4 of Appendix H of the revised EIS).

Treasury Metals Inc. - Goliath Gold Project Acoustic Environment RWDI#1602163 March 12, 2018

A noise analysis was conducted of the offsite vehicle movements for the construction and operations phases using traffic modelling methodology. Traffic information was extracted from the Goliath Gold Traffic Impact Study (i.e., "TIS") to obtain the estimated daily traffic volumes on Highway 17 and Anderson Road / Nursery Road both with and without the Project. Traffic noise modelling was conducted using the Ontario Ministry of the Environment and Climate Change's ORNAMENT roadway model.

Table 2-1 gives the traffic volumes used in the assessment. Highway 17 traffic volumes were estimated based on the peak hour turning movements from the TIS scaled up to an estimated annual average daily traffic value. Highway 17 volumes were assumed to be split 85%/15% between day/night and used truck percentages of 5% medium and 8% heavy trucks consistent with Ontario Ministry of Transport recommendations for provincial highways. The Project traffic was based on the daily volumes in Table 9 of the TIS. This table also provides the Project peak hour traffic and average non-peak hour traffic, which were used to estimate the amount of traffic in the day and night periods.

Given the projected vehicle route, Anderson Road and Nursery Road traffic volumes were assumed to be equal. Speed limits along Anderson and Nursery Road were assumed to be 60 km/hr and 80 km/hr along Highway 17.

The TIS identifies that the local traffic distribution will be modified with the presence of the mine, with a secondary morning (5-6am) and afternoon (6-7pm) peak hour in addition to the existing Highway 17 morning (11am-12pm) and afternoon (5-6pm) peak hours. Due to the early morning shift arrival for the mine (5am), there are two hours of mine traffic over the night-time (10pm-7am) period with the rest of the mine traffic predominantly occurring during the daytime (7am-10pm).

Table 2-1: Estimated Daily Traffic Volumes Used in Offsite Traffic Modelling

Phase	Road Segment [a]	AM/PM Peak Hour Volume [b]	Total Average Daily Volume	Total Daytime (0700h- 2200h) Volume [f]	Total Nighttime (2200h- 0700h) Volume [f]
Baseline	Anderson / Nursery Rd.	2/8	80 [c]	68	12
	Hwy 17 East of Anderson Rd.	339/359	3590 [c]	3052	539
	Hwy 17 West of Anderson Rd.	341/367	3670 [c]	3120	551
Construction	Anderson / Nursery Rd.	200/200	469 [d]	235	234
	Hwy 17 East of Anderson Rd.	110/332	2987 [e]	2822	165
	Hwy 17 West of Anderson Rd.	230/452	4187 [e]	3842	345
Operation	Anderson / Nursery Rd.	119/119	275 [d]	138	138
	Hwy 17 East of Anderson Rd.	95/322	2880 [e]	2737	143
	Hwy 17 West of Anderson Rd.	166/393	3590 [e]	3341	249

Notes: [a] Anderson Rd. and Nursery Rd. assumed to have same volumes due to route layout.

[b] Peak hour values determined from turning movement volumes in Traffic Impact Study (Appendix E of the revised EIS).

- [c] Average daily traffic (ADT) determined by assuming PM peak hour is 10% of total.
- [d] ADT determined from Table 9 of Traffic Impact Study for trips associated with Project.
- [e] ADT determined using combination of mine AM peak (5am, nighttime) and mine PM peak (6pm, daytime).
- [f] Day/Night split assumed to be 85%/15% based on typical MTO value for provincial highways. Similar truck splits assumed to be 5% medium and 8% heavy trucks per MTO for provincial highways.

During the construction phase, approximately 200 vehicles are expected to arrive during the mine's morning peak hour and then leave during the mine's afternoon peak hour. In between these peak hours, traffic is expected to be minimal. During the operations phase, a similar pattern exists although volumes are lower at 119 vehicles in the peak hour.

Treasury Metals Inc. - Goliath Gold Project Acoustic Environment RWDI#1602163 March 12, 2018

The Goliath Gold Traffic Impact Study (Appendix E of the EIS) indicates the vehicle traffic to and from the site will predominately be small vehicle traffic (94-96% of the annual trips are employee traffic & office supply trips), with larger vehicles larger vehicles accounting for 4-6% of the total annual traffic, which is approximately 15-19 trips per 24-hour period. The finished product leaving the mine site is infrequent (i.e., less than once daily).

To properly assess the influence of the relative change in traffic due to the Project, a baseline condition was established based on modelled traffic volumes to ensure consistent methodology for comparison purposes, as opposed to being based on ambient measurements in the original assessment. This approach is necessary since the traffic volumes that occurred during the measurements are unknown.

The results of the assessment are shown in Table 2-2. These results include the contributions due to blasting and steady-state source operations during both construction/site preparation and operations phases.

Table 2-2: Predicted Results including Offsite Traffic for Most-affected Receptors

Phase	Receptor [a]	L _{DN} without Project (dBA) [b]	L _{DN} with Project (dBA) [b]	Change in Percent Highly Annoyed	Meets Guideline?		
Construction/ Site	NR03	58	60	2.2%	Yes		
Preparation	NR04	60	61	0.9%	Yes		
	NR44	64	65	1.3%	Yes		
Operations	NR03	58	60	1.8%	Yes		
	NR04	60	61	0.7%	Yes		
	NR44	64	65	1.1%	Yes		

Notes: [a] Receptors in LSA most-affected by access road traffic.

[b] LDN after 10 dB adjustment for quiet rural area.

Results include contribution from blasting and steady-state sources during either phase.

Compared to the number of vehicles on Highway 17, the vehicles associated with the Project are not predicted to measurably change the background noise levels from existing traffic which is dominated by Highway 17. The change in percent highly annoyed is predicted to meet the guideline with the inclusion of traffic noise, blasting, and steady-state sources for each Project phase.

Treasury Metals Inc. - Goliath Gold Project Acoustic Environment RWDI#1602163 March 12, 2018

Although the guideline is predicted to be met, it is acknowledged that the shift change during construction / site preparation or operations phase will produce a notable change in local vehicle traffic, particularly along Anderson Road and Nursery Road. This change will lead to a short-term increase in noise for local residents during an hour where noise is not notable under the existing conditions (e.g., particularly during vehicle arrivals in the early morning hours for the shift start).

To assist with mitigating this effect, it is recommended that some consideration be given to managing the traffic flow. For example, staggered shift starts could be considered so vehicles do not all arrive in a single hour; bussing workers to the site during construction phases; carpooling could be encouraged.

3 ASSESSMENT OF BLASTING

Information request TMI_190-AE(1)-28 outlined recommended adjustments to the analysis of blasting in the environmental noise assessment and requested that the analysis be modified to include the adjustments.

Blasting produces a sound and vibration wave that rapidly decays as the blast energy disperses, and thus has only a short-term influence (i.e., less than 5-10 seconds) on local sound levels. Repeated blasting events within a single day could contribute to sound levels to create a notable change in longer-term sound exposures (e.g., 15-hour day, 9-hour night, or 24-hour levels). This project only anticipates one blast per day, hence the most critical effects are expected to be during short-term sound exposures such as one-hour levels (i.e., consistent with provincial guidelines). Over longer-term averaging periods, blasting is expected to be insignificant, but has been evaluated further.

According to the standard ISO 1996-1:2003 cited in the information request, blasting is identified as a "high-energy impulsive sound source" in accordance with Section 3.5.1 (i.e., "any explosive source where the equivalent mass of TNT exceeds 50 g", with examples that include quarry and mining explosions, sonic booms, demolition or industrial sources that use high explosives). This source category is different from the "highly impulsive sound source" defined in ISO 1996-1:2003 (i.e., the one that would apply the 12 dB adjustment identified in Table A.1) and is also consistent with provincial guidelines that exclude blasting as an impulsive source (i.e., NPC-103). Section 4.2.2 of the environmental noise assessment contained in Appendix H of the revised EIS incorrectly references the inclusion of a 12 dB penalty on this type of source. High-energy impulse sounds are assessed per the methods outlined in Annex B of ISO 1996-1:2003.

Annex B outlines how to determine the adjusted sound exposure level for high-energy impulse sounds based on its C-weighted sound exposure level. For blast-related sound exposures less than 61 dBC, the adjusted sound exposure level in dB is unchanged or less than the blast-related sound exposure.

As a result, blast-related sound exposures less than 61 dBC could conservatively be included in an acoustic assessment without adjustment.

Peak sound pressure levels of 78 dB have been predicted at the most affected receptor for this project. As shown in Figure 2, a typical blast lasts less than 0.1 seconds based on the image taken from Figure 14-7 of Construction Vibrations (2000) by Charles H. Dowding.

Figure 2: Excerpt from Construction Vibrations (Dowding, 2000) Showing Typical Blast Duration

If the blast event was conservatively assumed to release energy for 5 seconds at a sustained sound pressure of 78 dB, the resulting 15-hour sound exposure level would be 38 dB. It would be further conservative to assume this broadband sound to be A or C-weighted without changing its magnitude, i.e., giving 38 dBA or dBC. This sound exposure level would see no increase per the methods of ISO 1996-1, Annex B. Assuming it would be A-weighted and additive to the other construction noise would add further conservatism.

Based on the above, the peak sound pressure levels due to blasting at each receptor were converted to sound exposure levels and added to the predicted contributions of the other steady-state construction or operational noise levels. The resulting day-night sound exposures (LDN) changed by 1 dB or less with the addition of blasting, and resulted in minor increases to the change in percent highly annoyed. No conclusions were altered.

The predicted results with blasting included assessed to Health Canada guidelines for the construction and operations phases are presented in Tables 3-1 and 3-2 below. Details of the calculations are provided in Tables 3-3 and 3-4.

Table 3-1: Assessment of Construction and Site Preparation Noise to Health Canada Guidelines

4 SOUND LEVEL ADJUSTMENTS

Information request TMI_193-AE(1)-29 expressed concern that sound level adjustments for tonal, cyclic or quasi-steady impulsive sounds were not applied to the source data or receiver limits. It specifically refers to Ontario Ministry of the Environment and Climate Change (MOECC) document, NPC-104 Sound Level Adjustments, which outlines when source sound levels should be modified to account for particularly annoying qualities in the sound character.

The sound level adjustments outlined in NPC-104 include:

- An increase of 5 dB to source levels that exhibit an audible tonal quality, such as a whine, screech or buzz. According to MOECC guidance, a tone is a sound that exhibits a single dominant frequency. Examples of these sources include circular and chain saws (whine or screech), transformers (buzz), or sirens.
- An increase of 5 dB to source levels that exhibit an audible cyclical variation such as beating or
 other amplitude modulation. According to MOECC guidance, beating is the cyclical pulsation
 of sound that occurs with two tones at almost the same frequency. An example of beating
 noise sources would be two machines operating at almost the same speed.
- An increase of 10 dB to source levels where the source is considered to be quasi-steady
 impulsive. According to MOECC guidance, examples of these sources would include pavement
 breakers, riveting guns, and ineffectively muffled air compressors.

The above sound level adjustments are applied to the **source level** to account for the more annoying characteristics of the sound and are not used to adjust receiver limits, or otherwise. The adjustments are not cumulative and only one is applied per source. The information request appears to suggest that adjustments be made to the source levels or to lower the allowable receiver limits. Even if a source warranted an adjustment, it would only be made to that specific source in the analysis; it would be incorrect to adjust the receiver limit.

Per MOECC document NPC-103, the application of the NPC-104 adjustments is to be made based on the **observed**, **audible** character of a source **as perceived** at a receiver location; in other words, not based on the sound character as heard near the source, but as heard at the receiver. This distinction is important since a source's sound characteristics alter as it propagates through air to the receiver, so what is heard near the source is different once it reaches the receiver. Both atmospheric absorption and ground attenuation act to attenuate sound at varying rates by frequency which will alter the

audible qualities of the sound once it reaches a receiver. Furthermore, at increasing distance a source's volume diminishes and begins to blend in and be masked by the background sounds in an area. In practice this means many potentially annoying source characteristics dissipate and are no longer audible in the same way once they reach a receiver location.

Since the above adjustments are applied based on the observed qualities of sound, they are not typically applied to general broadband sources of noise, except where known to be a concern. Large electrical transformers, for example, are known to produce a buzz/tonal characteristic that is linked to resonance of its magnetic core and a 5 dB adjustment may be anticipated for receivers near the source. At large distances of several hundred meters however, even a transformer's unique tonal quality is no longer audible so the 5 dB adjustment would not apply if not observed.

As a result, it would be highly uncommon to apply sound level adjustments to a source's character without observed evidence. The sources in this assessment (i.e., including ventilation equipment, generators, building exhausts, on site vehicle traffic, and rock crushing equipment) were reviewed and are not known to exhibit the annoying characteristics outlined in NPC-104, and since no evidence exists in the reference sound data, no adjustments were applied to the source levels. This approach is consistent with industry practice and MOECC guidance.

Warning devices such as backup beepers and alarms, can be tonal but are exempt from evaluation per MOECC guidance as it is necessary they are heard for safety purposes. The noise source summary tables for each of the Project phases are provided in the respective sections (6.2: site preparation and construction; 7.2: operations; 8.2:" closure) of the Environmental Noise Assessment (included as part of Appendix H to the revised EIS).
