1 Introduction

Keefer Ecological Services Ltd. (KES) was retained by NWP Coal Canada Ltd. (NWP) to assess baseline vegetation and soil chemistry at the Crown Mountain Coking Coal Project (the Project) prior to development. The baseline chemistry can then be used to assess the potential effects and provide a basis for mitigation, management, and monitoring requirements for the Project. Interpretation of metal and Polycyclic Aromatic Hydrocarbons (PAH) chemical concentrations as tested by a qualified third-party analytical laboratory are to be conducted by a qualified third-party risk assessor for the purposes of informing the human and terrestrial wildlife health risk assessment for the Project. This report outlines the basis for plant species selection, field methodology, and results of the metal and PAH chemical analysis. This report also includes a compilation of additional baseline data that was collected in the local study area (LSA) to support the human health and wildlife risk assessment, including soil samples analysed for metal concentrations collected for the baseline soil classification and mapping program.

2 Plant Species Selection

Plant species selected for chemical analysis include species that are consumed by humans and/or wildlife, have specific characteristics related to chemical uptake, are known to be sensitive or indicator species of change, and/or are potentially most affected by the Project. Plants selected for metal and PAH analyses are presented in Table 2-1. Important forage species for large mammals, such as elk, deer, moose, and bear, were selected for sampling as these mammals consume large volumes of food across a wide range of habitat types. Further, to provide information relating to human health, vegetation species were selected based on traditional and present-day use by humans, with focus on berry species. Specific tissue of important foods (e.g., foliage/branch tips, berries) for wildlife and humans available for consumption during the summer and winter is also presented in Table 2-1. Key rationale for the selection of vegetation species as bio accumulators or vegetation species demonstrating a potential pathway of concern for wildlife species and/or humans is outlined in Table 2-2. Species were not selected with input from First Nations, as consultation had not been initiated at the time of collection.

Table 2-1 Plant species selected for metal and polycyclic aromatic hydrocarbon (PAH) analysis based on wildlife use and traditional plant/human use.

Latin name	Common name	Component to Sample	Wildlife Use	Traditional Plant/Human Use	Summer Availability	Winter Availability
<i>Amelanchier alnifolia</i>	Saskatoon	foliage + branches	bighorn sheep, deer, elk, grizzly bear, moose	x	x	x
		berries			x

Table 2-2 Rationale for species selection.

	Species	Common Name	Sample	Rationale
Wildlife	<i>Amelanchier alnifolia</i>	Saskatoon	twigs and leaves	Eaten by elk (USDA, 1999), moose (Wall, Belisle & Luke, 2011), and white-tailed deer (BC Government, 2000)
	<i>Carex</i> sp.	sedge	whole plant	Eaten by grizzly bear (McLellan & Hovey, 1995), elk (USDA, 1999), moose (Wall, Belisle & Luke, 2011), and white-tailed deer (BC Government, 2000)
	<i>Equisetum arvense</i>	horsetail	whole plant	Eaten by grizzly bear (McLellan & Hovey, 1995), elk (USDA, 1999), moose (Wall, Belisle & Luke, 2011), and white-tailed deer (BC Government, 2000)
	<i>Populus balsamifera</i>	black cottonwood	twigs and leaves	Eaten by elk (USDA, 1999), moose (Wall, Belisle & Luke, 2011), and white-tailed deer (BC Government, 2000)
	<i>Rubus parviflorus</i>	thimbleberry	twigs and leaves	Eaten by elk, deer, moose and bears (USDA, 2012)
	<i>Salix</i> sp.	willow	twigs and leaves	Eaten by elk (USDA, 1999), moose (Wall, Belisle & Luke, 2011), and white-tailed deer (BC Government, 2000)
	<i>Sheperdia canadensis</i>	soopolallie	twigs, leaves and berries	Eaten by grizzly bear (McLellan & Hovey, 1995), elk (USDA, 1999), moose (Wall, Belisle & Luke, 2011), and white-tailed deer (BC Government, 2000)
	<i>Vaccinium membranaceum</i>	huckleberry	twigs, leaves and berries	Eaten by grizzly bear (McLellan & Hovey, 1995), elk (USDA, 1999), moose (Wall, Belisle & Luke, 2011), and white-tailed deer (BC Government, 2000)
Humans	<i>Amelanchier alnifolia</i>	Saskatoon	berries	Kuhnlein & Turner (2009): Traditional Plant Foods of Canadian Indigenous Peoples
	<i>Rubus parviflorus</i>	thimbleberry	berries	Kuhnlein & Turner (2009): Traditional Plant Foods of Canadian Indigenous Peoples
	<i>Sheperdia canadensis</i>	soopolallie	berries	Kuhnlein & Turner (2009): Traditional Plant Foods of Canadian Indigenous Peoples
	<i>Salix</i> sp.	willow	whole plant	Traditional food source (First Nation Health Authority, n.d.)
	<i>Vaccinium membranaceum</i>	huckleberry	berries	Hobby & Keefer (2010): A black huckleberry case study in the Kootenay region of British Columbia
Accumulators	<i>Equisetum arvense</i>	horsetail	whole plant	Cannon, Shacklette & Bastron (1968): Metal absorption by Equisetum - Equisetum consistently accumulates zinc
	<i>Salix</i> sp.	willow	leaves, stems, roots	Han, Kim & Shin (2013): Bioaccumulation and physiological response of five willows to toxic levels of Cadmium and Zinc Gough <i>et al.</i> (2003): Cadmium mobility and bioaccumulation by willow

3 Methods

3.1 Field Sample Collection

3.1.1 Baseline Chemistry Vegetation and Soil Survey

The baseline sampling program was developed in general accordance with the British Columbia Field Sampling Manual (Ministry of Water, Land and Air Protection [BC MWLAP], 2013) and a Health Canada guidance document for including country foods in human health risk assessments (Health Canada, 2017). The guidance documents were used to develop study objectives, sample design and quality assurance/quality control (QA/QC) protocols for the sampling of soil and vegetation.

Vegetation samples were collected from 55 unique locations in August and September 2017 and in July 2019 to capture a range of seasonality and to target appropriate plant tissue collection. As such, the sample collection dates targeted the peak periods for new shoots, leaves, and/or berries of each plant species. Table 3-1 presents the number of sampling locations per species, which included Saskatoon (*Amelanchier alnifolia*), beaked sedge (*Carex utriculata*), common horsetail (*Equisetum arvense*), black cottonwood (*Populus balsamifera* subsp. *trichocarpa*), rose species (*Rosa* sp.), thimbleberry (*Rubus parviflorus*), black elderberry (*Sambucus racemosa* var. *melanocarpa*), willow species (*Salix* sp.), soopolallie (*Shepherdia canadensis*), and black huckleberry (*Vaccinium membranaceum*). The plant tissue collected per species at each sampling location is also presented in Table 3-1.

Sampling locations were selected based on the distribution of plant species throughout the Project area (Figure 3-1). For the sake of efficiency, soil and vegetation samples were paired with the terrestrial ecosystem mapping (TEM), soil and terrain baseline studies, where possible. The soil and terrain baseline study program aimed at collecting samples in proximity to and within the Project infrastructure footprint. Other samples were collected in sensitive areas (e.g., wetlands). Occasionally, two plant species were found in the same sampling location and thus a single GPS waypoint was taken to represent both species ([Appendix 1](#)).

Table 3-1 Number of sampling locations and plant tissue collected per vegetation species.

Latin Name	Common Name	Abbreviation	Number of Sampling Locations***	Plant Tissue/Soil Collected	Number of Samples Submitted for Metals Analysis	Number of Samples Submitted for PAH Analysis

* Soil sample associated with multiple vegetation samples.

** Sample was not submitted for PAH analysis as insufficient sample volume was available.

*** Sample locations are shown in Figure 3-1 which correspond to Appendix 1 and Tables 4-5 and 4-7.

**** SAMBRAC samples mislabeled as SAMBCAE in field (5 out of 6 samples).

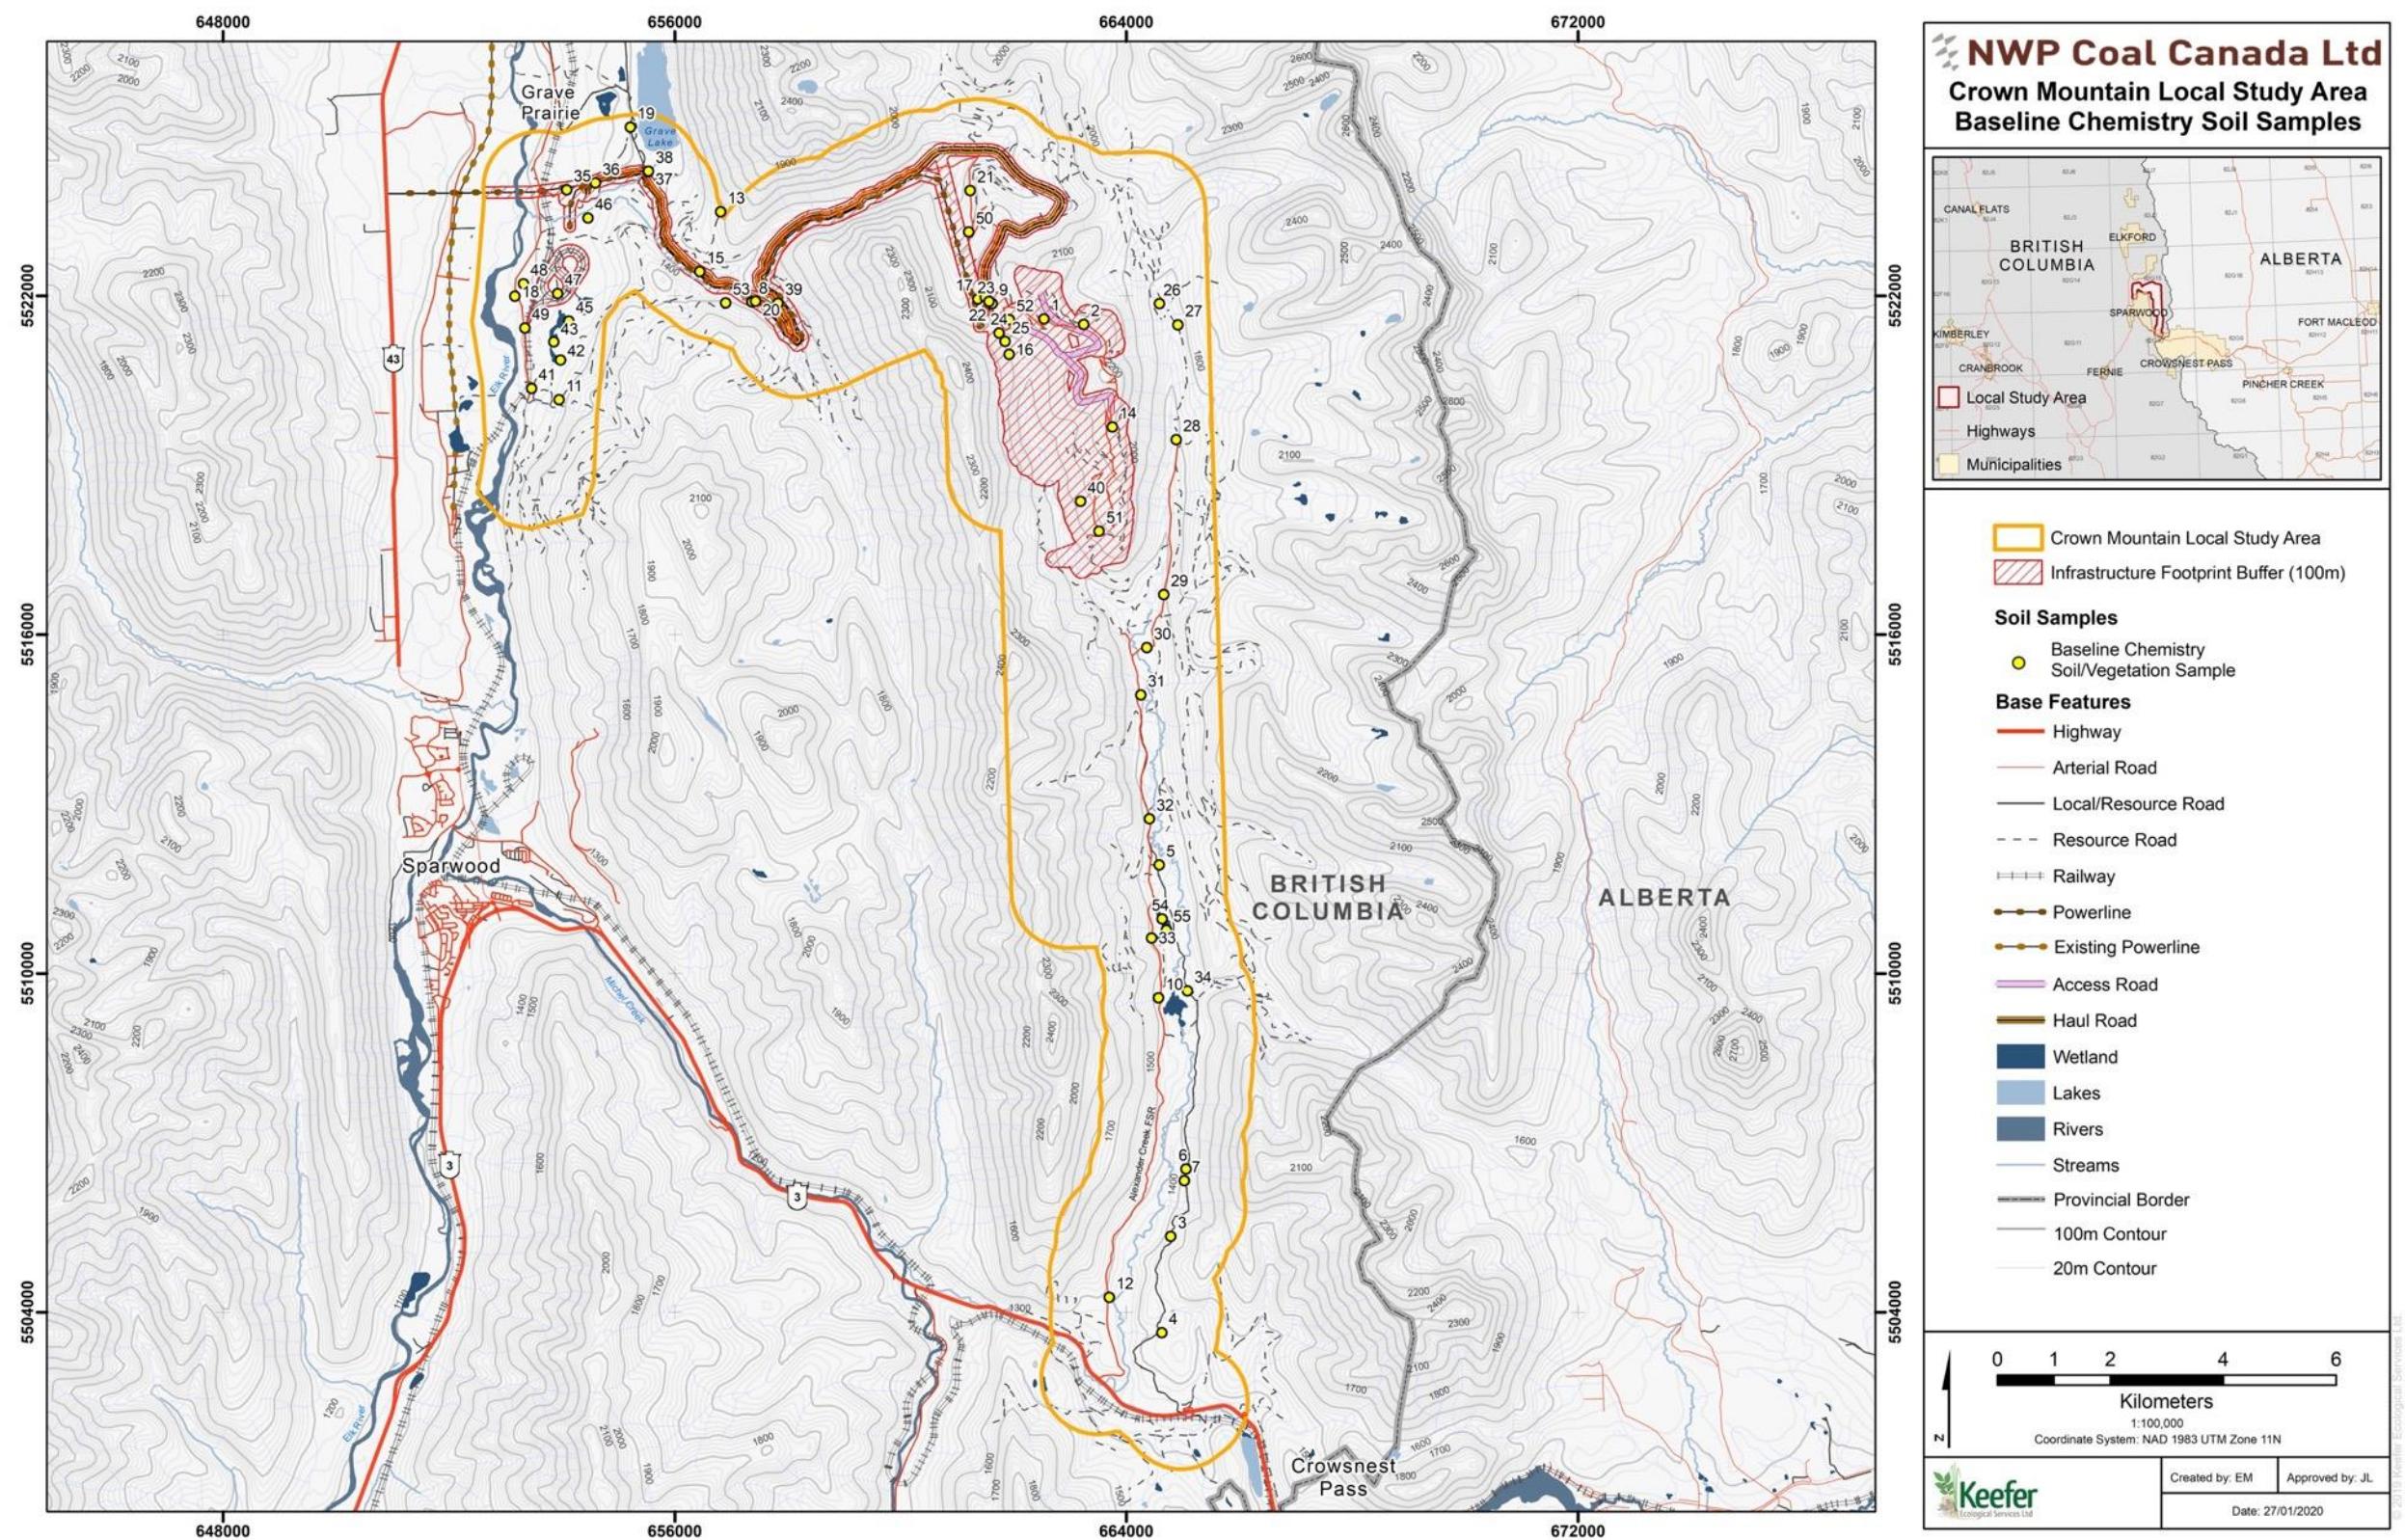

Figure 3-1. Vegetation and soil sample locations association with baseline chemistry surveys within the Project LSA.

Approximately 10 grams (g) of plant tissue sample was collected by hand and placed into a clean, labelled Ziploc® bag. A new pair of latex or nitrile gloves was worn at each of the sampling locations to reduce the risk of sample contamination. A ceramic knife was used to collect plant tissue when necessary and distilled water was used to clean the knife between samples. At each vegetation sampling location, soil samples were collected from within 2 meters (m) of the vegetation sample. Soil samples were collected between 0-30 centimeters (cm) in depth from the soil surface, as the top 30 cm of soil typically contains the greatest rooting density. If two plant species were in the same area, additional soil samples were not collected; rather, both plant species were associated with the same soil sample (Appendix 1). One, 125 millilitre (mL) composite soil sample was collected between 0-30 cm and soil texture, coarse fragment content, soil drainage, and the primary vegetation community were recorded at each sampling location (Appendix 2). A combination of A and B horizons for mineral soils ($n = 60$) and the upper 30 cm of organic soil horizons ($n = 5$) were sampled. A stainless-steel shovel was used to dig into the soil at a depth of approximately 50 cm. A plastic trowel was then used to scrape away soil exposed to the shovel to reduce the risk of contamination. An additional plastic trowel was used to collect soil for analysis and latex, or nitrile gloves were worn to reduce the risk of sample contamination. The shovel and plastic trowels were cleaned using distilled water between samples. Vegetation and soil samples were stored in coolers with ice packs and immediately shipped for analysis to ALS Global in Burnaby, BC, following sample collection. As an additional quality control measure, four random field duplicate tissue samples were collected at a subset of sampling locations throughout the LSA.

3.1.2 Baseline Soil Classification and Mapping

At representative soil pit locations, soil samples from different depths (e.g., leaf litter, 0-15 cm mineral, and rarely subsurface mineral) were collected using a small stainless-steel trowel and placed directly into labelled plastic bags or 125 mL soil sample jars. The soil samples were stored in coolers with ice packs prior to shipment to ALS Environmental. The results of this survey are included herein to ensure all available chemical data for soil samples throughout the LSA are considered in the human and terrestrial wildlife health risk assessment. Soil sample locations associated with these surveys are presented in Figure 3-2.

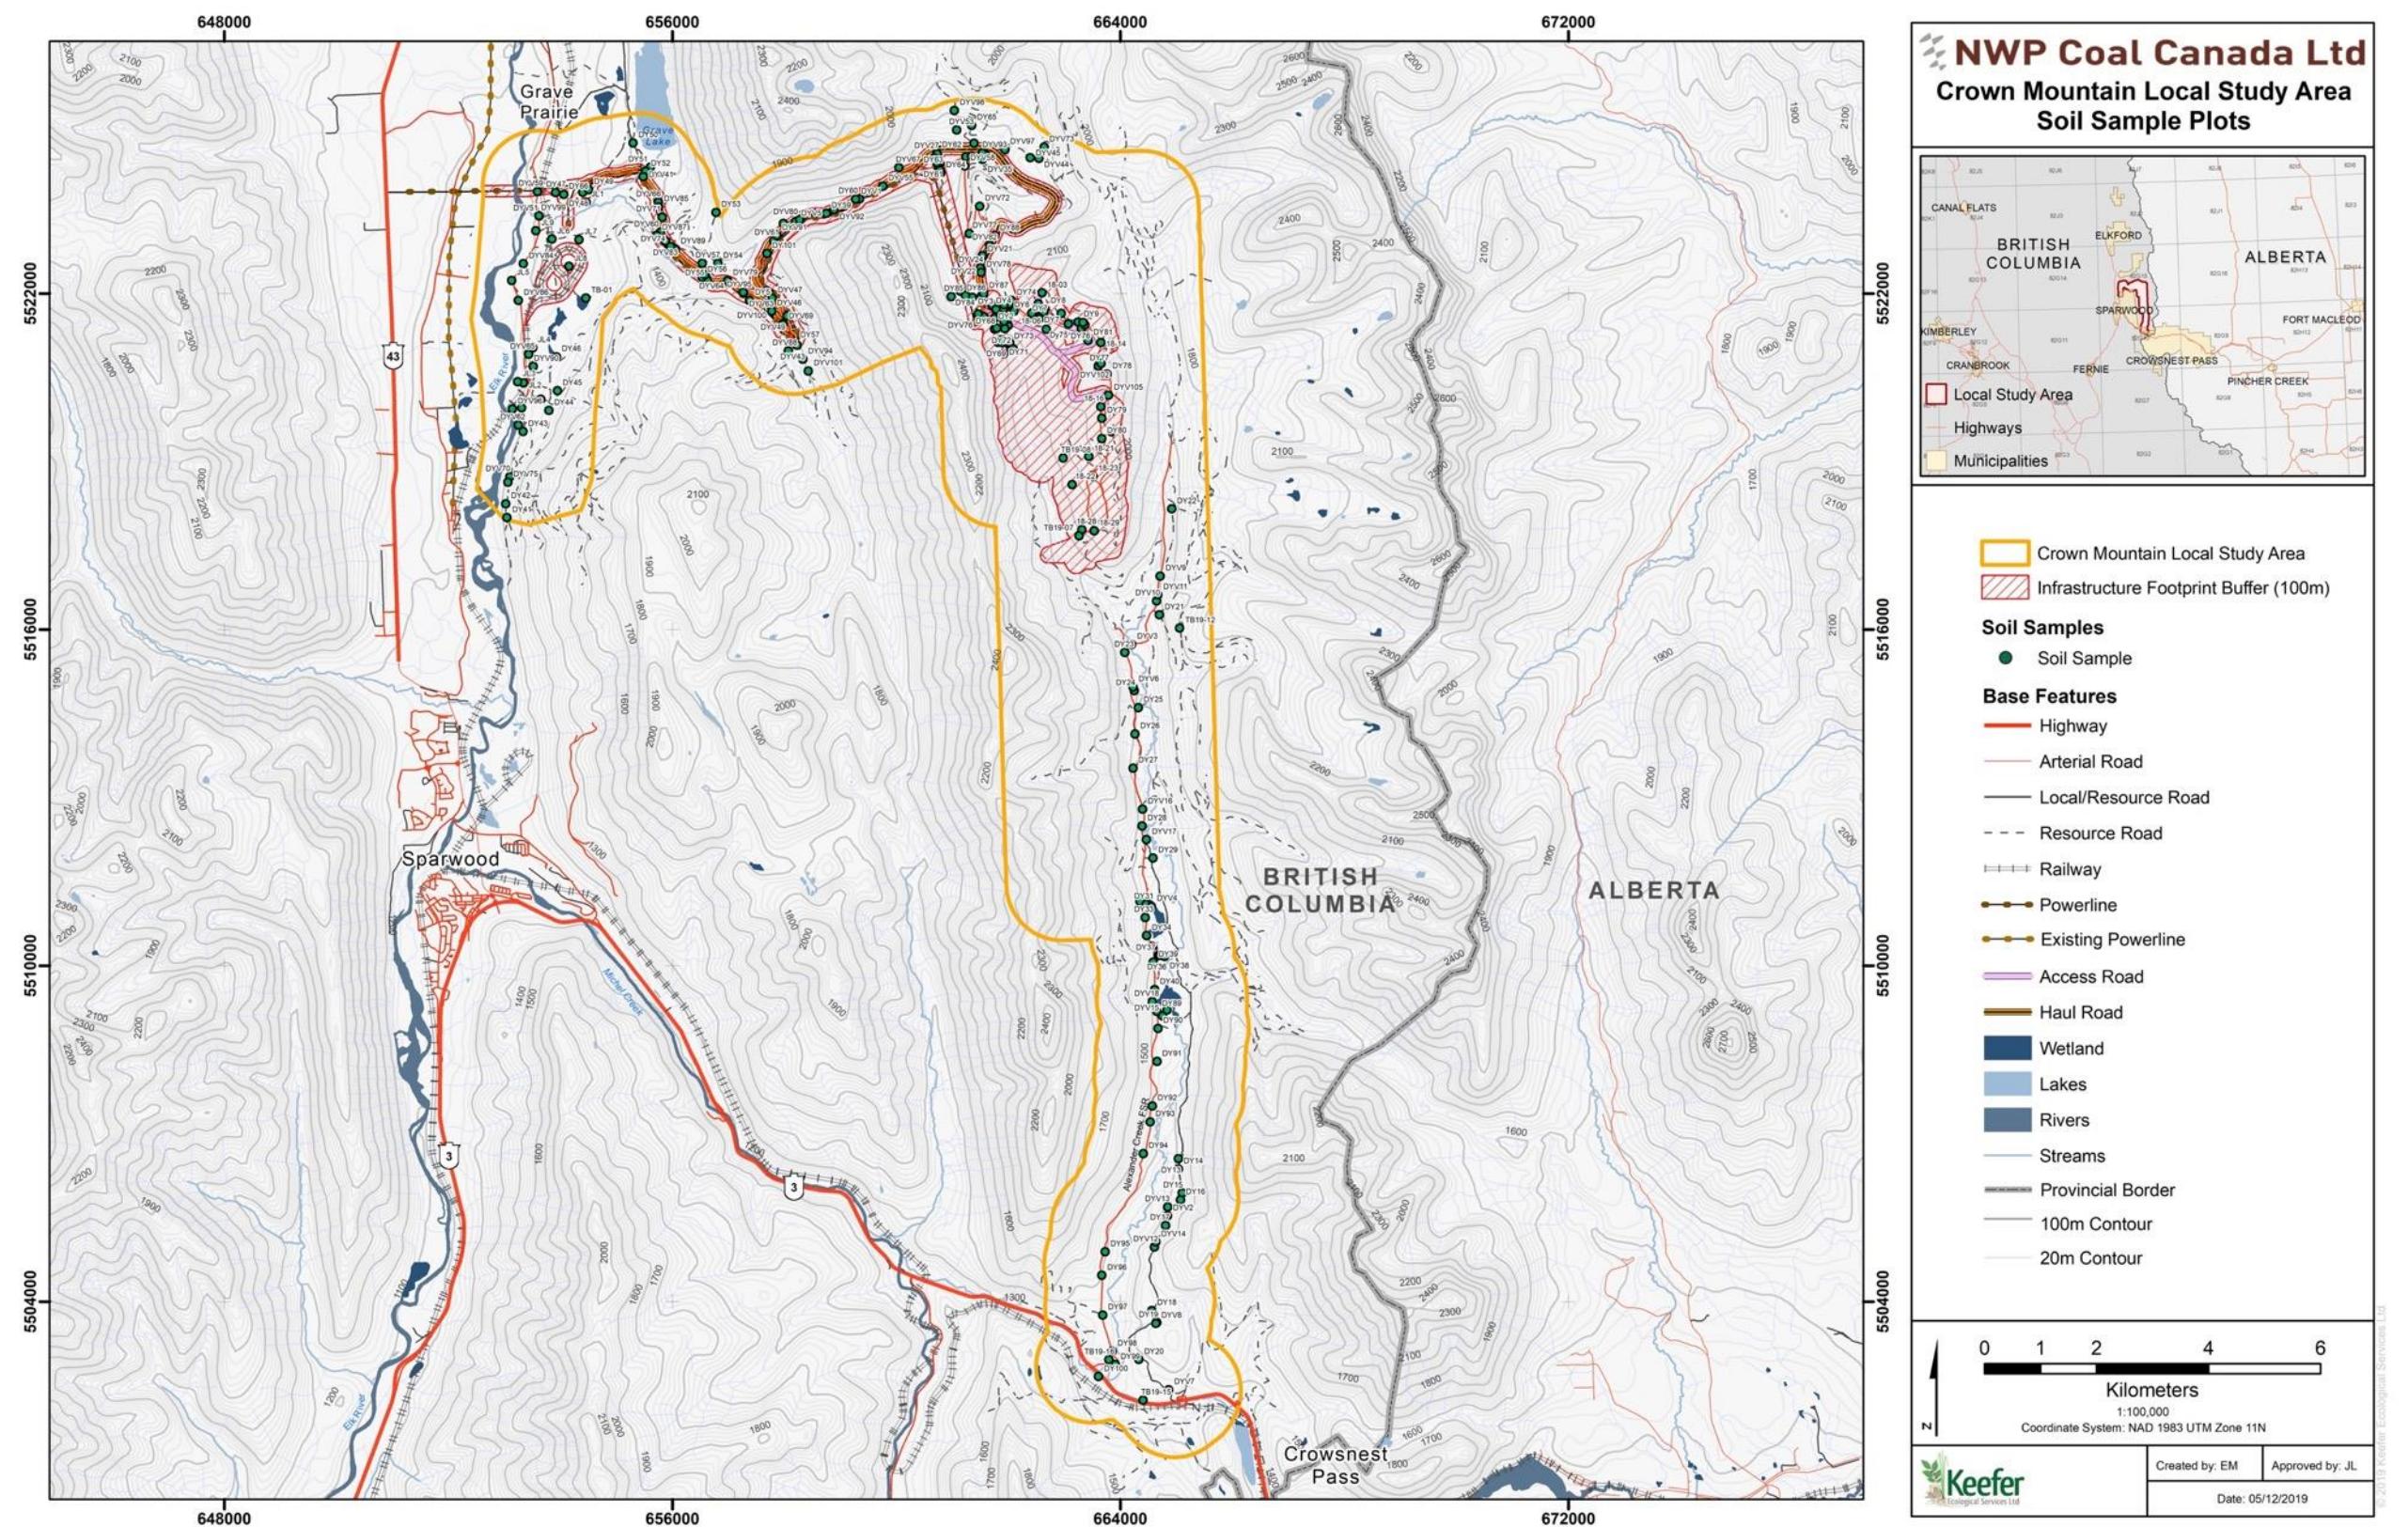

Figure 3-2. Soil sample locations association with baseline soil classification and mapping surveys within the Project LSA.

3.2 Laboratory Analysis

ALS Environmental conducted moisture content and metal analyses on all vegetation samples and moisture content, pH, and metal analyses on all soil samples. Test methods used are outlined in as per the Certificates of Analysis (COA) L1970983, L1974841, L198616, L198617, L198619, L1984966, L2003527, L2318167 for the vegetation and soil sampling and L1981208, L2137302, L2318167 for the soil classification and mapping baseline sampling (Appendix 4).

Table 3-2 Laboratory testing methods for soil and tissue samples.

Test Description	Test Method	Method Reference
Mercury in Soil	CVAFS ¹	EPA 200.2/1631E (modified)
Mercury in Tissue	CVAFS (dry)	EPA 200.3, EPA 245.7

% Moisture in Tissue	Gravimetrically	Puget Sound WQ Authority, Apr 1997
Moisture in Soil	Gravimetrically	CWS for PHC in Soil – Tier 1
PAH in Soil	GCMS ³	EPA 3570/8270
PAH in Tissue	GCMS	EPA 3540, 3630, 8270
pH in Soil	1:2 Soil:Water Extraction	BC WLAP Method: Electrometric, Soil

Metal concentrations in soil and plant tissue used EPA Method 6020 which is used to describe the multi-elemental determination of analytes by Inductively Coupled Plasma – Mass Spectrometry (ICP-MS) in environmental samples. The method measures ions produced by a radiofrequency inductively coupled plasma. Analyte species originating in liquid are nebulized and the resulting aerosol is transported by argon gas into the plasma torch. Ions produced in the plasma are sorted according to their mass-to-charge ratio (EPA, 1998). Modifying this method to include collision and reaction cells extends its capability by allowing the selective attenuation or removal of problematic interferences (McCurdy & Woods, 2004).

PAH analysis was only conducted on the first of each vegetation sample and the associated soil sample collected per plant species. This was done chronologically for each sample (e.g., AMELALN-01, CAREX-01). The rationale for this being that the much of the study area has not been previously disturbed and thus PAH levels were not expected to exceed acceptable levels as per the BC Contaminated Sites Regulation (CSR, BC Reg. 375/96, 2019) or Canadian Council for the Ministry of Environment guideline (CCME, 2010) for corresponding land use. Sampling proceeded under the understanding that if PAH level exceedances were identified; additional sampling would take place.

Lists of metals and PAH parameters analyzed by ALS Environmental for both soil and vegetation samples are presented in Appendix 3. Of the 21 PAH parameters analyzed for vegetation samples and 24 parameters analyzed for soil samples, four of the parameters (Acenaphthene d10, Chrysene d23, Naphthalene d8 and Phenanthrene d10) were used to spike samples, and refer to the percentage recovered from the extraction and analysis process. These parameters are compared to Acenaphthene, Chrysene, Naphthalene, and Phenanthrene in each sample as a method for quality control. Two additional parameters, Benzo(a)pyrene Total Potency Equivalent (B(a)P TPE) and the Index of Additive Cancer Risk (IACR), were calculated for soil samples in accordance with the CCME (2010) guidelines.

The B(a)P TPE represents the sum of estimated cancer potency relative to B(a)P for all potentially carcinogenic PAH parameters (i.e., Benz(a)anthracene, Benzo(a)pyrene, Benzo(b+j+k)fluoranthene, Benzo(g,h,i)perylene, Chrysene, Dibenz(a,h)anthracene and Indeno{1,2,3-c,d}pyrene). B(a)P TPE for each

¹ Cold vapor atomic fluorescence spectrometry

² Collision/reaction cell inductively coupled plasma – mass spectrometry

³ Gas chromatography with mass spectrometric detection

soil sample is calculated by multiplying the concentration of each PAH in the sample by its corresponding B(a)P potency equivalence factor. The IACR assesses potential threats to potable groundwater water quality from leaching carcinogenic PAH mixtures from soil. The IACR is calculated by dividing the soil concentration of each carcinogenic PAH by its soil quality guideline of potable water component value, which are then added together (CCME, 2010).

On occasion, detection limits were increased on a per sample basis due to limited sample amount, high moisture content, dilutions due to high concentration of test analytes, dilution due to sample matrix effects (e.g., chemical interference, colour, turbidity), and analytical interferences⁴. This was particularly common in the analysis of PAH in vegetation samples. Occurrences of a detection limit being raised above the standard detection limit for some parameters are shown in the raw analytical data presented in Table 4-5, Table 4-7, Table 4-11 and Table 4-12. Listed detection limits used by ALS Environmental for both metal and PAH parameters for soil and vegetation samples are shown in Appendix 5.

3.3 Quality Assurance/Quality Control

For each COA, ALS Environmental included QC samples with qualifiers and comments describing their intra-laboratory quality control with respect to a random assortment of metal parameters (e.g., molybdenum, chromium, manganese). Further QA/QC was completed through the submission and analysis of duplicate vegetation samples. The results of the duplicate sample analysis are expressed as Relative Percent Difference (RPD); an indicator of laboratory precision and sample heterogeneity. The lower the RPD value, the more precise the laboratory analysis.

$$RPD = \frac{|sample - duplicate|}{mean} \times 100$$

In accordance with BC MWLAP (2013), duplicate samples with a larger variation than 20% for soil, or 30% for vegetation indicate high sample variability which may be attributed to laboratory analysis, sampling technique (applicable for soil samples only) or natural sample heterogeneity. ALS Environmental noted high levels of sample heterogeneity overall.

3.4 Data Analysis

Microsoft Excel was used to conduct data analysis on metal concentrations of vegetation samples per plant species. Average and standard deviation of metal concentrations was determined per species. A two-tailed t-test of unequal variances was conducted between the foliage/branch tips and berries of fruit-bearing shrubs to assess whether there was a statistically significant difference in metal concentrations. The two-tailed t-test assumed that the data were normally distributed, with unequal variances. The detection limit was used for vegetation samples which had metal levels below the detection limit in order to perform data analysis. Additionally, vegetation and soil samples were assessed individually to highlight which samples exhibited metal and/or PAH concentration exceedances relative to the provincial (BC Reg. 375/96, 2019) and federal (CCME, 2010) environmental thresholds for the land use.

4 Results

4.1 Metals

Provincially, soil metal concentrations are regulated under the *Environmental Management Act Contaminated Sites Regulation* (CSR, BC Reg. 375/96, 2014; Table 4-1,

⁴ See *Detection limit policies: Reducing the chance of false positives due to sample-specific issues*. Retrieved from <http://www.alsglobal.com>

Table 4-2). Federally, the Canadian Soil Quality Guidelines for the Protection of Environmental and Human Health (CCME, 2006) are used to evaluate the consequences of development associated with a variety of land uses (Table 4-3). As the Project falls within both provincial and federal jurisdiction, both thresholds were considered.

Table 4-1 Matrix numerical soil standards for wildlands natural (presented in µg/g = mg/kg).

Constituent	Human Health Protection (Intake of contaminated soil)	Environmental Protection (Toxicity to invertebrates and plants)

Note that there are no provincial or federal guidelines for the following analytes: Bi, Bo, Ca, Fe, Li, Mg, P, K, Na, Sr, S, Ti and Zr.

4.1.1 Soil Results: Baseline Chemical Surveys

The Certificates of Analysis provided by ALS Environmental (L1970983, L1974841, L198616, L198617, L198619, L1984966, L2003527, L2318167) for soil samples collected in association with vegetation sampling present results and document methods (Appendix 4). All baseline chemistry soil samples with guideline exceedances are presented in Figure 4-1.

Tin (Sn) and tungsten (W) metals occurred in concentrations below the detection limit for all samples collected during these surveys, 2.0 and 0.50 mg/kg, respectively. Sulphur (S, n=48) and bismuth (Bi, n=37) were also consistently found in concentrations below the detection limit (1,000 and 0.02 mg/kg, respectively; Table 4-5).

On a per sample basis, a soil sample (mineral material) associated with a rose vegetation sample (sample 38, ROSA-05) collected from the upland area surrounding a wetland located at the intersection of Harmer and Grave Lake Roads, of which 17 (Sb, Bi, B, Co, Cu, Fe, Mo, Ni, Se, Ag, Na, S, Sn, W, Zn and Zr) of the 34 metal parameters analyzed exhibited the lowest concentrations; followed by a soil sample (mesic organic material) associated with a beaked sedge vegetation sample (sample 45, CAREX-09), collected from a wetland in the western portion of the LSA (south of Grave Creek, west of the Elk River), exhibited the lowest metal concentration for 13 (Al, Ba, Be, Bi, Cr, Li, Mn, Ag, Tl, Sn, W, V and Zr) of the 34 metal parameters analyzed (Table 4-4). A soil sample (mineral material) associated with a rose vegetation sample (sample 48, ROSA-06), collected east of Valley Service Road, approximately 2 km south of the intersection with Harmer Road, exhibited the highest metal concentration for five (As, Be, Ni, K and V) of the 34 metal parameters analyzed; followed by a soil sample (mesic organic material) associated with a willow vegetation sample (sample 44, SALIX-06), of which four (B, Se, Na and Sr) of the 34 metal parameters analyzed exhibited the highest concentrations (Table 4-4).

The mesic organic soil sample associated with beaked sedge (sample 25, CAREX-02), collected from an open water wetland at the base of Gaff Peak, exhibited a barium concentration of 503 mg/kg, which exceeds the CCME guideline for residential/parkland (500 mg/kg; Table 4-3). Similarly, the mineral soil

sample associated with soopolallie (sample 11, SHEPCAN-02), collected immediately east and uphill of the reclaimed Teck land in the west of the LSA, was found to contain a barium concentration (601 mg/kg) that also exceeds the CCME guideline. A third mineral soil sample (sample 31, CAREX-03/EQUIARV-05), collected from a wetland south of the confluence of West Alexander and Alexander Creeks, was found to contain 401 mg/kg barium which exceeds the provincial wildlands natural guideline for the protection of ecological health (Table 4-1).

The mineral soil sample associated with a rose vegetation sample (sample 48, ROSA-06), collected from a forested site east of Valley Service Road approximately 2 km south of the intersection with Harmer Road, was found to contain concentrations of arsenic (12.7 mg/kg) and nickel (50.6 mg/kg) that exceeded the CCME residential/parkland guideline (Table 4-3).

The mesic organic soil sample associated with both willow and black cottonwood vegetation samples (sample 4, SALIX-01/POPUBAL-01) was found to contain a cobalt concentration (45 mg/kg) that exceeded the provincial wildlands natural guideline for the protection of ecological health (Table 4-1).

Thirteen soil samples collected throughout the LSA, representing 11% of soil samples analysed (n = 123), were found to contain concentrations of selenium that exceed either the CCME guidelines (1.0 mg/kg), the provincial guidelines (1.5 mg/kg), or both. These samples include 4 (SALIX-01/POPUBAL-01), 5 (POPUBAL-02), 8 (SALIX-03), 25 (CAREX-02), 31 (CAREX-03/EQUIARV-05), 34 (CAREX-04), 37 (CAREX-05), 42 (CAREX-07), 43 (CAREX-08), 44 (SALIX-06), 45 (CAREX-09), 54 (SALIX-07) and 55 (CAREX-10). Exceedances are detailed in Table 4-4 .

Table 4-4 Soil selenium concentration exceedances from baseline chemistry sampling.

55 (beaked sedge)	✓	✓

Selenium is leached from coal waste rock into surface water features throughout the Elk Valley (CCME, 2009); it is therefore expected that samples collected from sites associated with surface water features (i.e., wetlands, ponds, creeks, rivers) may have increased selenium concentrations. Each of the 13 samples that exceeded the CCME regulatory guidelines for selenium, were near surface water features. Coal geology exists within the LSA and is a likely natural contributor to elevated selenium levels.

Table 4-5 Summary of soil samples collected in association with baseline chemical surveys. Samples with highest (■) and lowest (□) concentrations (mg/kg) are indicated, lowest values at the detection limit (□) are also indicated. Where thresholds for analytes exist: CCME (2018) guideline exceedances noted with red highlight; CSR (2019) exceedances noted with yellow highlight.

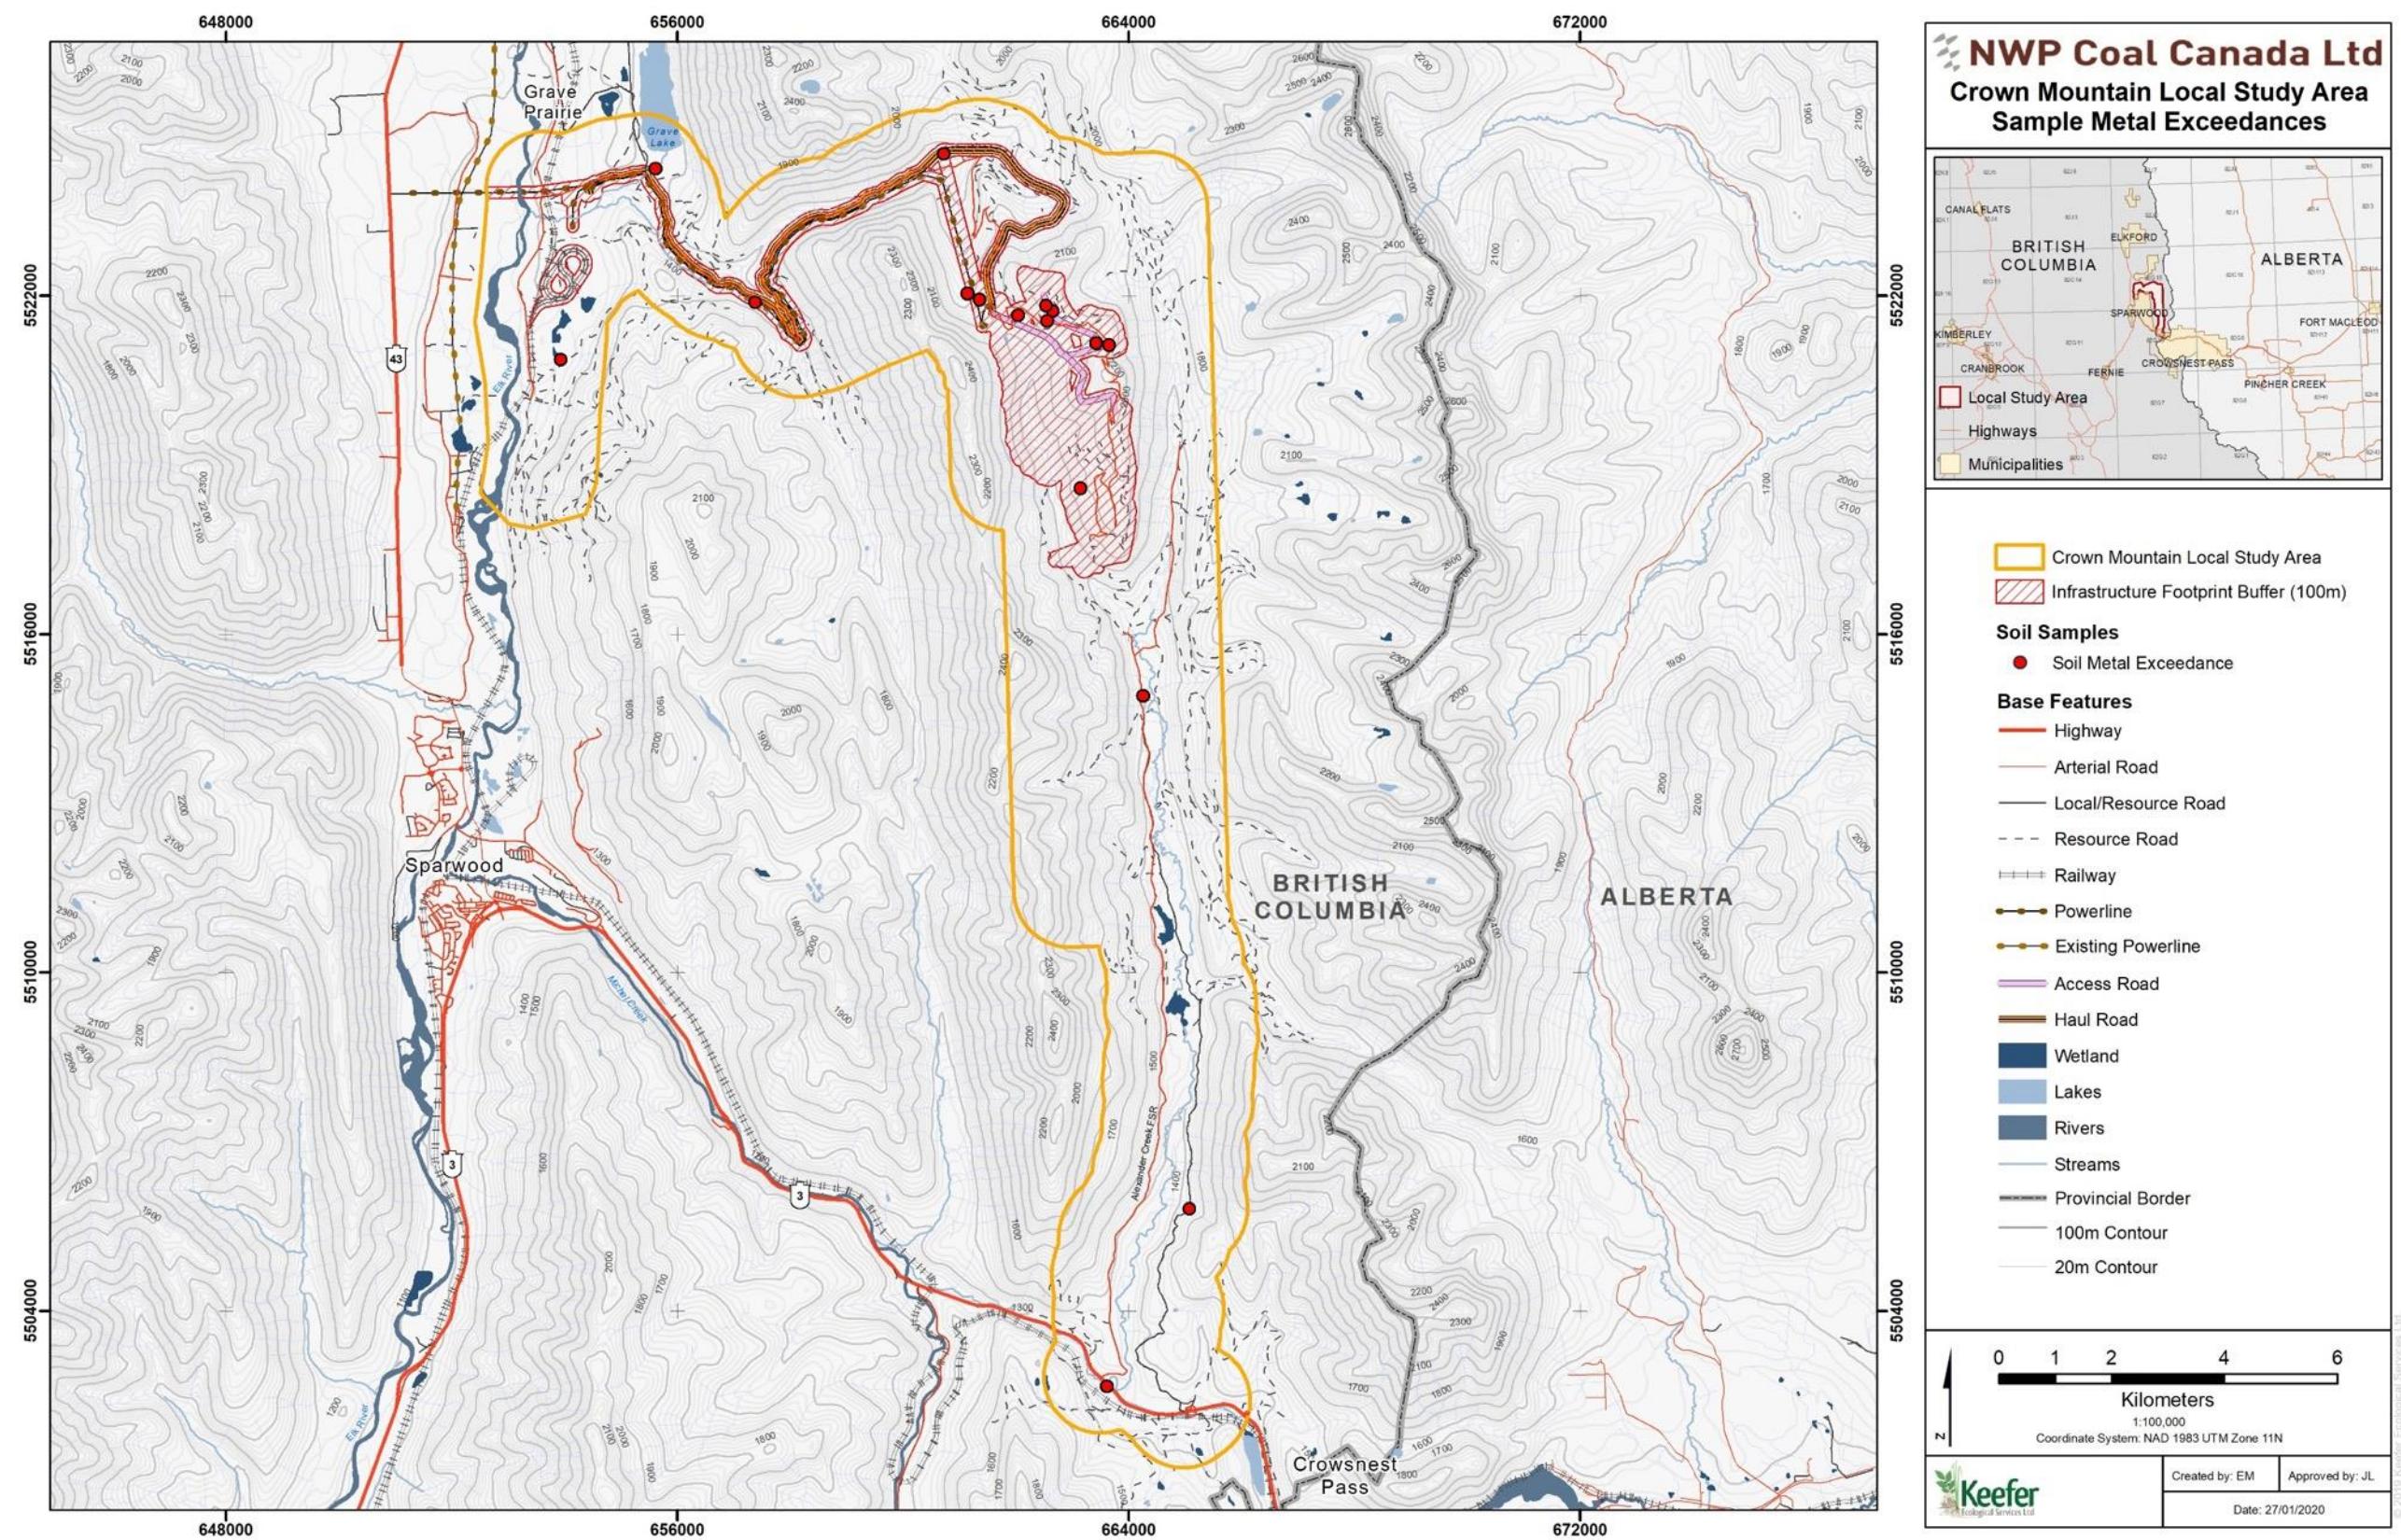

Figure 4-1. Soil sample locations association with baseline chemistry surveys found to contain metal concentrations above federal and/or provincial guidelines.

4.1.2 Soil Results: Baseline Soil Classification and Mapping

The Certificates of Analysis provided by ALS Environmental (L1981208 and L2137302) for soil samples collected in association with vegetation sampling present results and document methods (Appendix 4). All baseline chemistry soil samples with guideline exceedances are presented in Figure 4-2.

Tin (Sn) and tungsten (W) metals occurred in concentrations below the detection limit for all samples collected during these surveys, 2.0 and 0.50 mg/kg, respectively. Sulphur (S, n=55), boron (B, n=34), sodium (Na, n=33) and bismuth (Bi, n=32) were also consistently found in concentrations below the detection limit (1,000, 5.0, 50 and 0.02 mg/kg, respectively; Table 4-7).

On a per sample basis, a mineral soil sample associated with DY70 collected south and slightly uphill of an open water wetland at the base of Gaff Peak, of which 11 (Ba, Bi, B, Cu, Mo, K, Se, Na, S, Sn and W) of the 34 metal parameters analyzed exhibited the lowest concentrations; similarly, a mineral soil sample associated with DY80, collected from the Crown Mountain ridgeline, approximately 2 km straight-line distance south from the summit of Crown Mountain, exhibited the lowest metal concentration for 11 (Bi, B, Ca, Li, Se, Ag, Na, S, Sn, W, Zr) of the 34 metal parameters analyzed (Table 4-7). A mineral soil sample associated with 18-22-IIC, from a depth of approximately 3.5 m from the northwest wall of drill pad 18-22 (western face of the Crown Mountain ridge, south of the summit), exhibited the highest metal concentration for six (As, Cd, Co, Ni, V and Zn) of the 34 metal parameters analyzed; followed by a mineral soil sample associated with DY81 (0-15 cm), collected in a high elevation wetland below the summit of Crown Mountain, of which four (Ba, Be, P and Ag) of the 34 metal parameters analyzed exhibited the highest concentrations (Table 4-7).

The mineral soil sample at DY6 (0-15 cm), collected from a forested slope south of the Branch C Road (1970 m elevation), was found to contain concentrations of aluminum (40,010 mg/kg) that exceeded the provincial wildlands natural guideline for the protection of human health (40,000 mg/kg; a threshold for the protection of ecological health has not been defined) and barium (547 mg/kg) that exceeded the CCME guideline for residential/parkland (500 mg/kg). The mineral soil sample at DY83 (0-15 cm), collected from the cutblock along the Branch C road (below the road), was also found to contain concentrations of barium (40,000 mg/kg) that matched the threshold in the provincial guideline. Mineral soil samples from DY8 (0-8 cm) and DY81 (0-15 cm) had barium concentrations that exceeded the CCME guideline, 508 and 656 mg/kg, respectively. Additionally, mineral soil samples from DY16 (0-15 cm), DY45 and 18-22-IIC (350+ cm) were found to contain concentrations of barium that exceeded the provincial guideline (Table 4-6).

The mineral soil sample collected at DY88 (0-15 cm), a forested east-facing slope above the Branch C road, was found to contain concentrations of manganese (4,230 mg/kg) that exceeded the provincial wildlands natural guideline for ecological health (2,000 mg/kg). The mineral soil sample collected at DY46 (0-15 cm), an upland area adjacent to a wetland in the west of the LSA, was found to contain

concentrations of thallium (1.22 mg/kg) and zinc (257 mg/kg) that exceeded the CCME guideline, 1.0 and 250 mg/kg, respectively.

The subsoil sample (350+ cm depth) collected at drill pad 18-22 on the west-facing slope of the Crown Mountain ridge was found to contain additional exceedances including, barium (as above), arsenic (15.2 mg/kg), nickel (84.7 mg/kg) and zinc (320 mg/kg), all of which exceed the CCME guideline for residential/parkland.

As with the chemistry results presented in Section 4.1.1, selenium levels exceeded CCME residential/parkland and/or provincial wildlands natural guidelines at numerous locations (Table 4-6).

Table 4-6 Soil selenium concentration exceedances from baseline soil mapping.

These samples correlate with many of the samples from Section 4.1.1 and with known coal geology surface features that are likely to produce selenium as they are weathered in place. For example, DY5 which corresponds to sample number 8 (willow species; Table 4-4) which also has elevated levels of selenium in the soil. DY8 corresponds to a coal seam that is exposed at the land surface and is likely producing selenium through weathering. Samples DY24 and 46 are also in similar locations to baseline chemistry samples that had selenium exceedances (Table 4-4). Samples DY51, DY81, DY84 and DY100 are in proximity to surface water features (i.e., wetlands, ponds, creeks, rivers) which may be contributing to the elevated selenium levels observed.

As with the soil sampled in conjunction with the baseline chemical (soil and vegetation) sampling, a large amount of variability is seen, with most parameters varying about ten-fold and calcium varying almost a thousand-fold.

Table 4-7 Summary of soil samples collected in association with baseline soil classification and mapping surveys. Samples with highest (■) and lowest (□) concentrations (mg/kg) are indicated; lowest values at the detection limit (□) are also indicated. Where thresholds for analytes exist: CCME (2018) guideline exceedances noted with red highlight; CSR (2019) exceedances noted with yellow highlight.

* Detection Limit adjusted from 1.0 mg/kg due to sample matrix effects (e.g., chemical interference, colour, turbidity).

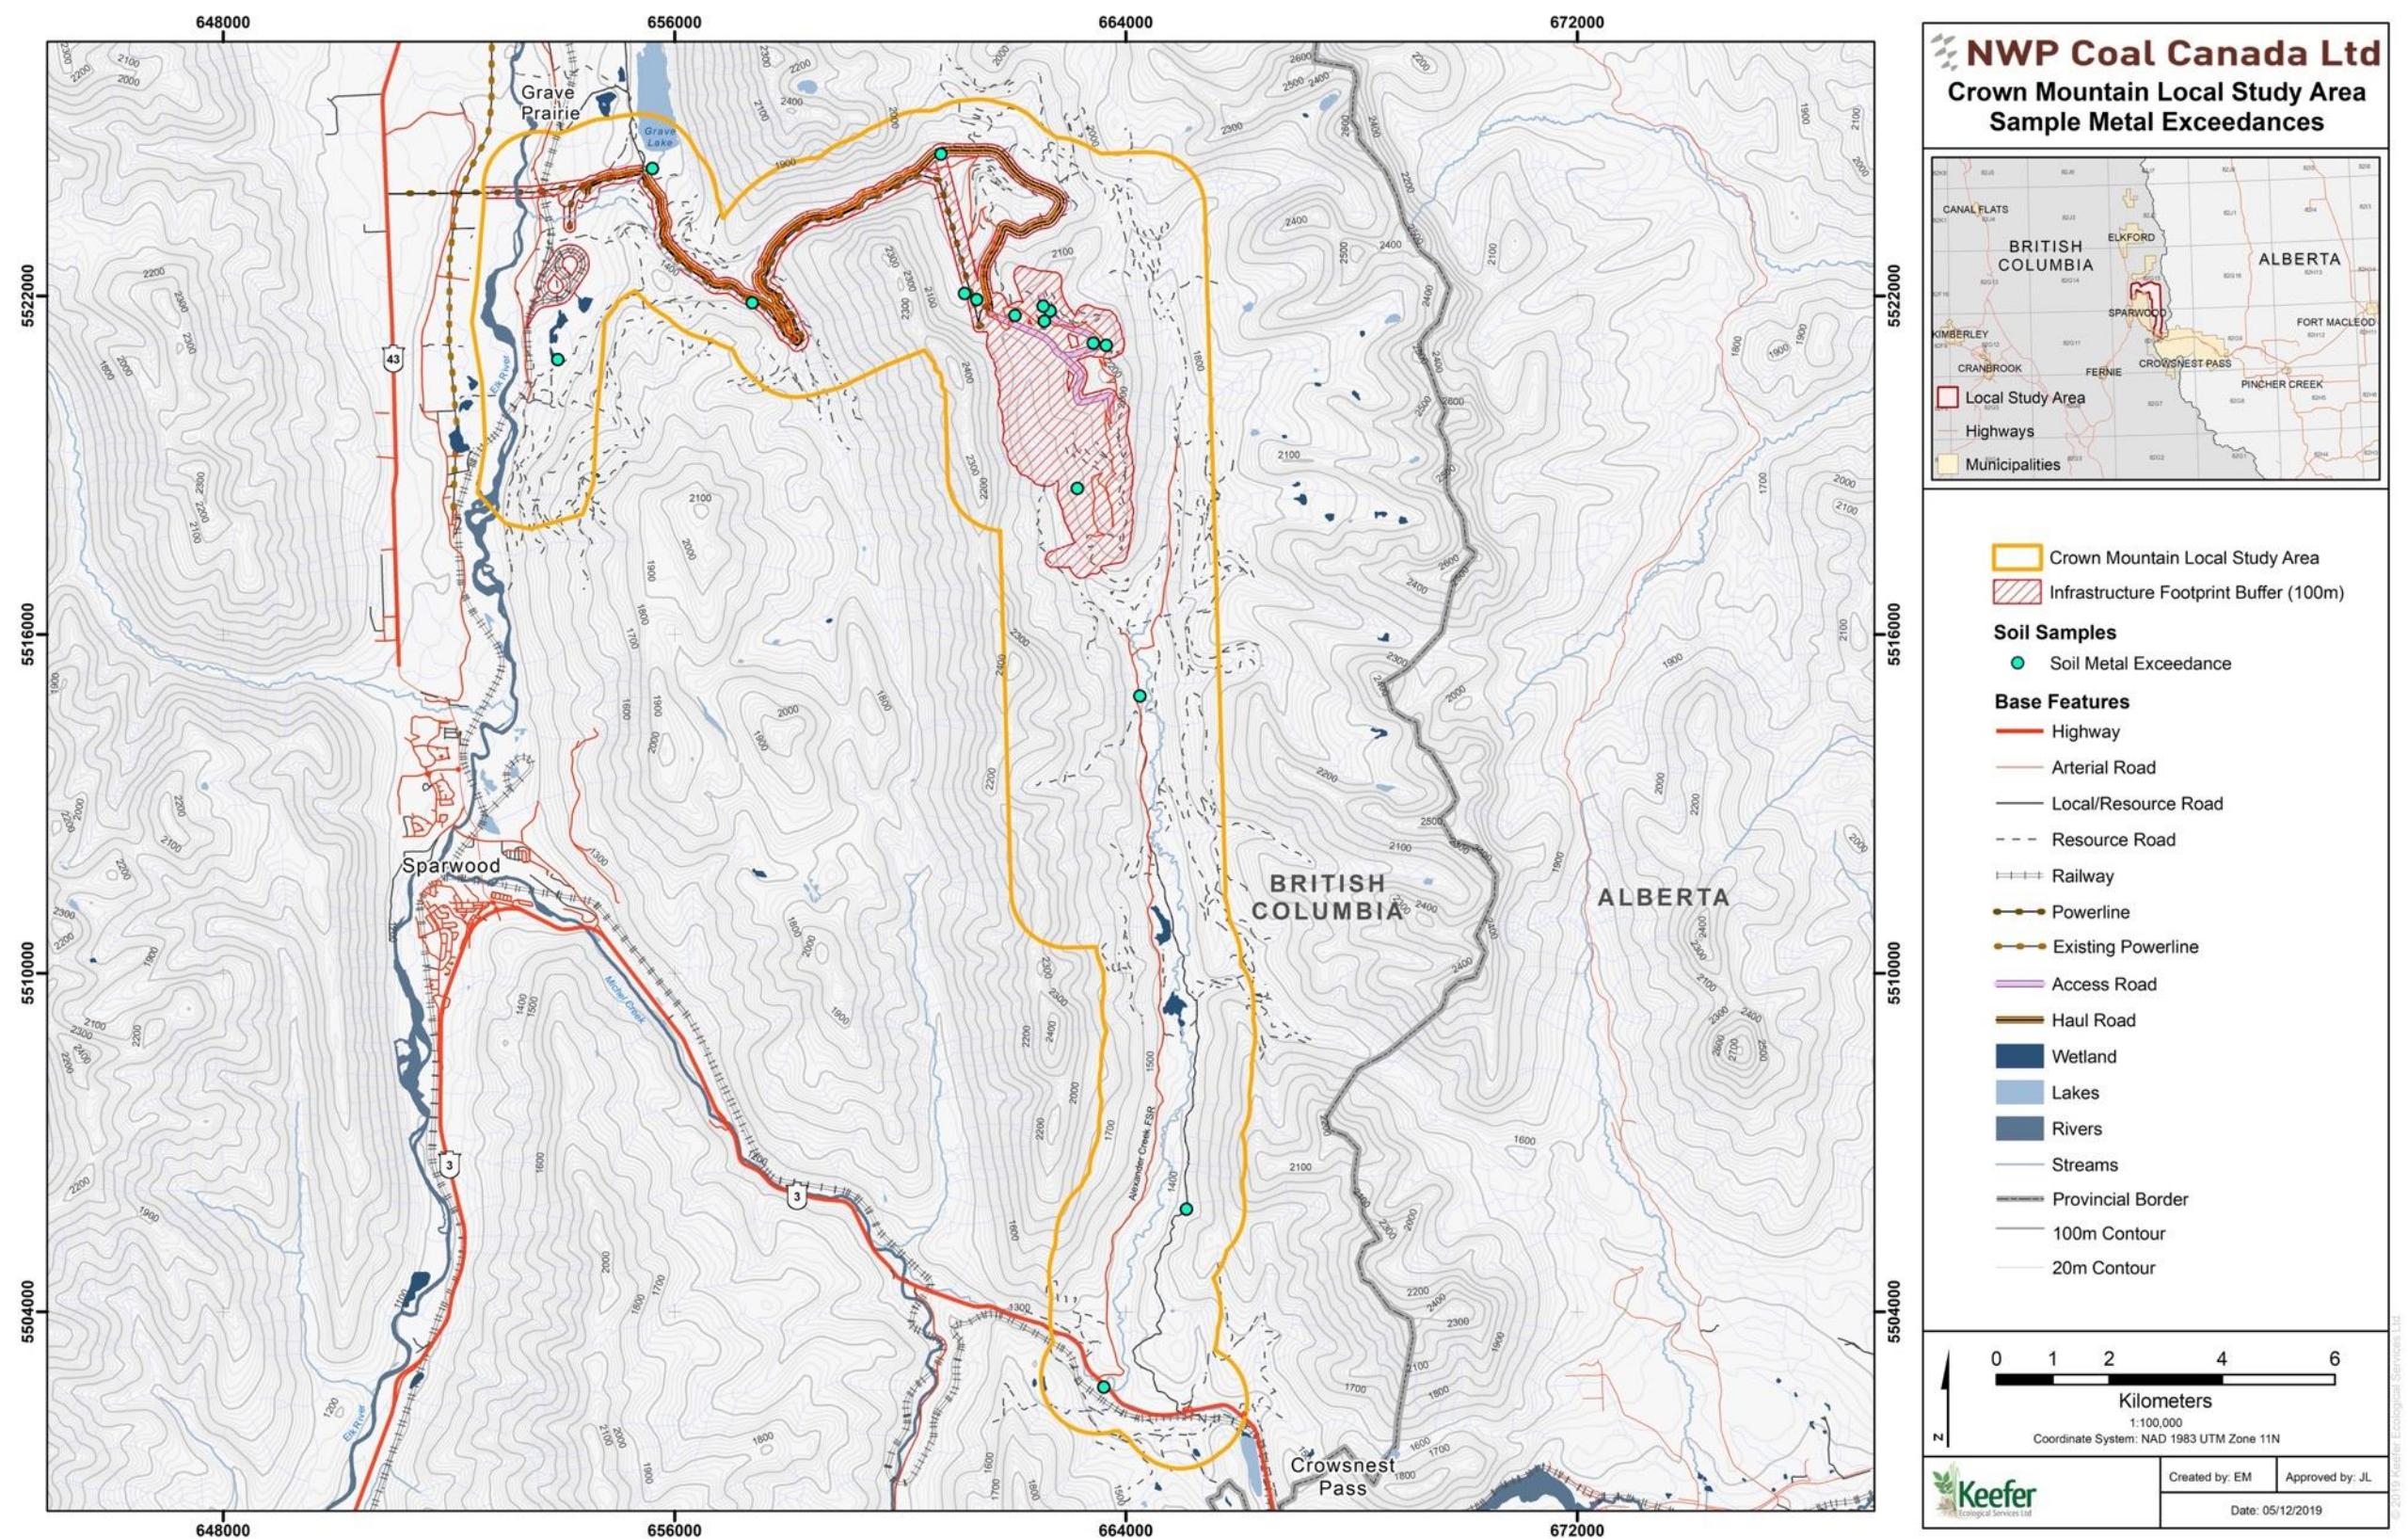

Figure 4-2. Soil sample locations association with baseline soil classification and mapping surveys found to contain metal concentrations above federal and/or provincial guidelines.

4.1.3 Vegetation Results

The Certificates of Analysis (L1970983, L1974841, L1978616, L1978617, L1978619, L1984966 and L2318167), provided by ALS Environmental, for plant tissue samples is presented in Appendix 4. No guidelines exist for levels of metals in vegetation with respect to environmental or human health, so interpretation of results is not definitive.

Bismuth (Bi) and tellurium (Te) metals occurred in concentrations below the detection limit for all samples collected during the baseline soil and vegetation chemistry surveys, 0.010 and 0.020 mg/kg, respectively. Beryllium (Be, n=88), lithium (Li, n=88), zirconium (Zr, n=87), tin (Sn, n=73) and antimony (Sb, n=67) were also consistently found in concentrations below the detection limit (0.010, 0.50, 0.20, 0.10 and 0.010 mg/kg, respectively; Table 4-8).

On a per tissue sample basis, a soopolallie berry sample (sample 10) collected from bedrock outcrop at the edge of an east-facing cutblock on the western side of the Alexander Main Forest Service Road (FSR), exhibited the lowest concentrations for 20 of the 33 metal parameters analyzed (Sb, As, Ba, Be, Bi, Cs, Cr, Co, Pb, Li, Mg, Mn, Na, Te, Ti, Sn, U, V, Zn and Zr). Samples of rosehips (sample 13, western edge of the Grave Creek canyon), thimbleberries (sample 7, eastern-facing toe slope of the continental divide range), elderberries (sample 16, avalanche chute below Gaff Peak) and huckleberries (sample 22, cutblock along Branch C) were also found to contain consistently low metal concentrations (Table 4-8). A composite sample of huckleberry foliage/branch tips (sample 51) collected from a west-facing bedrock and coal seam exposure near the southern extent of the Crown Mountain ridge, was found to contain the highest concentrations of six (Al, Be, Fe, Pb, U and V) of the 33 metal parameters analyzed (Table 4-8).

On average, horsetail vegetation (EQUIARV) was found to contain the highest concentrations of five (Ca, Cs, Pb, Rb, Se) of 33 metal parameters analyzed, followed by willow (SALIX) foliage/branch tips (4/33). Huckleberry (VACCMEM) berry samples were found to contain the highest concentrations of 12 of 33 metal parameters (Al, As, Cd, Cs, Cr, Co, Fe, Pb, Mn, Sn, U and V), followed by Saskatoon berries (AMELALN, 7/33). Conversely, Saskatoon foliage/branch tips were found to contain the lowest levels of six (As, Cr, Pb, Ni, Rb and V) of 33 metal parameters, on average. Soopolallie berry samples were found, on average, to have the lowest concentrations of eight (Ba, Ca, Cu, Mg, Mn, Sr, V and Zn) of the 33 metal parameters.

Table 4-8 Summary of metal analysis for vegetation samples. Samples with highest (■) and lowest (□) concentrations (mg/kg) are indicated, lowest values at the detection limit (□) are also indicated.

26	SHEPCAN-04	Plant	36.1																																

Six foliage/branch tip samples were collected from all fruit-bearing shrub species between 2017 and 2019 sampling events. However, due to a lack of available berry tissue found throughout the LSA at the time of sampling, six berry samples were not collected from all fruit-bearing shrubs. Only five berry samples were collected from rose and thimbleberry; three berry samples from Saskatoon; and two berry samples from huckleberry. The differences in sample size are accounted for in the two-tailed, unequal variance t-test between fruit (e.g., berries) and foliage/branch tips (Table 4-9). Species that do not produce berries (beaked sedge, horsetail, black cottonwood, and willow species) cannot be analyzed in the same manner and as such, were compared using the mean and standard deviation of their metal concentrations (Table 4-10).

Among the fruit-bearing shrubs, the majority of metal concentrations found within the berries were equal to or less than metal concentrations in the foliage/branch tips (Table 4-9). However, tin concentrations in thimbleberry, elderberry, soopolallie, and black huckleberry berries were found to have higher concentrations than the foliage/branch tips. Additionally, the berries of Saskatoon were found to have higher concentrations of arsenic, boron, cobalt and potassium than the foliage/branch tips. Concentrations of all metal parameters between the rosehips and foliage/branch tips of the rose species collected were not found to differ significantly.

Table 4-9 Average ± standard deviation of metal levels in plant tissue (mg/kg) collected from fruit-bearing shrubs throughout the LSA. Statistical significance between foliage/branch tips and berries of shrubs is presented. (↓) and (↑) indicates berries had metal levels significantly less or greater than the foliage/branch tips, (-) indicates no significant difference, (=) indicates that average concentrations were found to be equal.

	Saskatoon (<i>Amelanchier alnifolia</i>)			Rose species (<i>Rosa</i> sp.)			Thimbleberry (<i>Rubus parviflorus</i>)			Elderberry (<i>Sambucus racemosa</i> var. <i>melanocarpa</i>)			Soopolallie (<i>Shepherdia canadensis</i>)			Black huckleberry (<i>Vaccinium membranaceum</i>)

4.2 PAH

4.2.1 Soil Samples

The COAs (L1970983, L19778617 and L1974841), provided by ALS Environmental, showing PAH concentrations in the collected soil samples are presented in Appendix 4. In total, seven soil samples were submitted for PAH analysis, following the first chronological sample submission procedure discussed in Section 3.2 (Figure 4-3). Soil from sample location 4 was associated with both willow and black cottonwood vegetation samples (SALIX-01 and POPUBAL-01), as both species were found growing on the soil that was sampled. A representative soil sample for common horsetail was not submitted in error as the first horsetail vegetation sample was associated with POPUBAL-03 (the third black cottonwood) soil sample. However, common horsetail grows alongside beaked sedge at soil sample location 24 (CAREX-01), at which PAH concentrations were analyzed. A representative soaproot sample (SHEPCAN-01) was also not submitted in error.

Of the 18 PAH parameters analyzed, 14 of the parameters exhibited concentrations below the detection limits for all submissions (Table 4-11, Appendix 4). Additionally, both the B[a]P TPE and the IACR parameters were below the detection limit for all soil samples, demonstrating low carcinogenic risk to humans having direct contact with soil within the LSA (CCME, 2010).

All soil samples for the Benzo(b&j)fluoranthene parameter were found to contain concentrations below the detection limit (0.010 mg/kg; Table 4-11) with one exception. One mesic organic soil sample (sample 4) collected within an organic soil unit on the east side of Alexander Creek, north of Highway #3, was slightly above the detection limit with a concentration of 0.011 mg/kg. The residential/parkland guideline maximum is 1.0 mg/kg for the Benzo(b&j)fluoranthene parameter (CCME, 2010); this sample value is below the guideline level by a hundred-fold. Further the provincial guideline for wildlands natural threshold value is 0.65 mg/kg. This sample also exhibited the highest concentrations in the 2-methylphthalene and Naphthalene parameters, at 0.040 mg/kg and 0.013 mg/kg, respectively. At present, CCME does not have soil quality guidelines for 2-methylphthalene; the provincial guidelines also lack sufficient data to determine a threshold value for the protection of ecological health. The provincial threshold for the protection of human health is 100 mg/kg for 2-Methylnaphthalene (CSR, 2019).

One other sample submitted for PAH analysis yielded results above the detection limit; the soil sample collected near an exposed coal seam northwest of the summit of Crown Mountain (sample 1). The soil sample exhibited the highest concentration for the Phenanthrene parameter at 0.053 mg/kg. The environmental health guidelines (CCME, 2010) indicate that the maximum acceptable Phenanthrene concentration for residential/parkland is 0.046 mg/kg; however, this value represents the soil quality guideline for the protection of freshwater life. The value may be used for terrestrial soil quality where potential impacts to nearby surface water is a concern. Where there is no potential risk to freshwater, the

threshold for Phenanthrene is 43.0 mg/kg⁶. The same applies to Naphthalene; where risk to freshwater exists, the threshold is 0.013 mg/kg, in the absence of risk to freshwater the threshold is 8.8 mg/kg. Provincially, only a guideline for Phenanthrene exists (3 mg/kg for the protection of ecological health; CSR, 2019).

Detection limits were raised for two samples (VACCMEM-01 and SALIX-01) due to co-eluting interference.

⁶ This guideline is considered provisional (CCME, 2010).

Table 4-11 Summary of PAH data analysis for soil samples. Samples with highest (■) concentrations (mg/kg) are indicated. Raised detection limits (□) are also indicated.

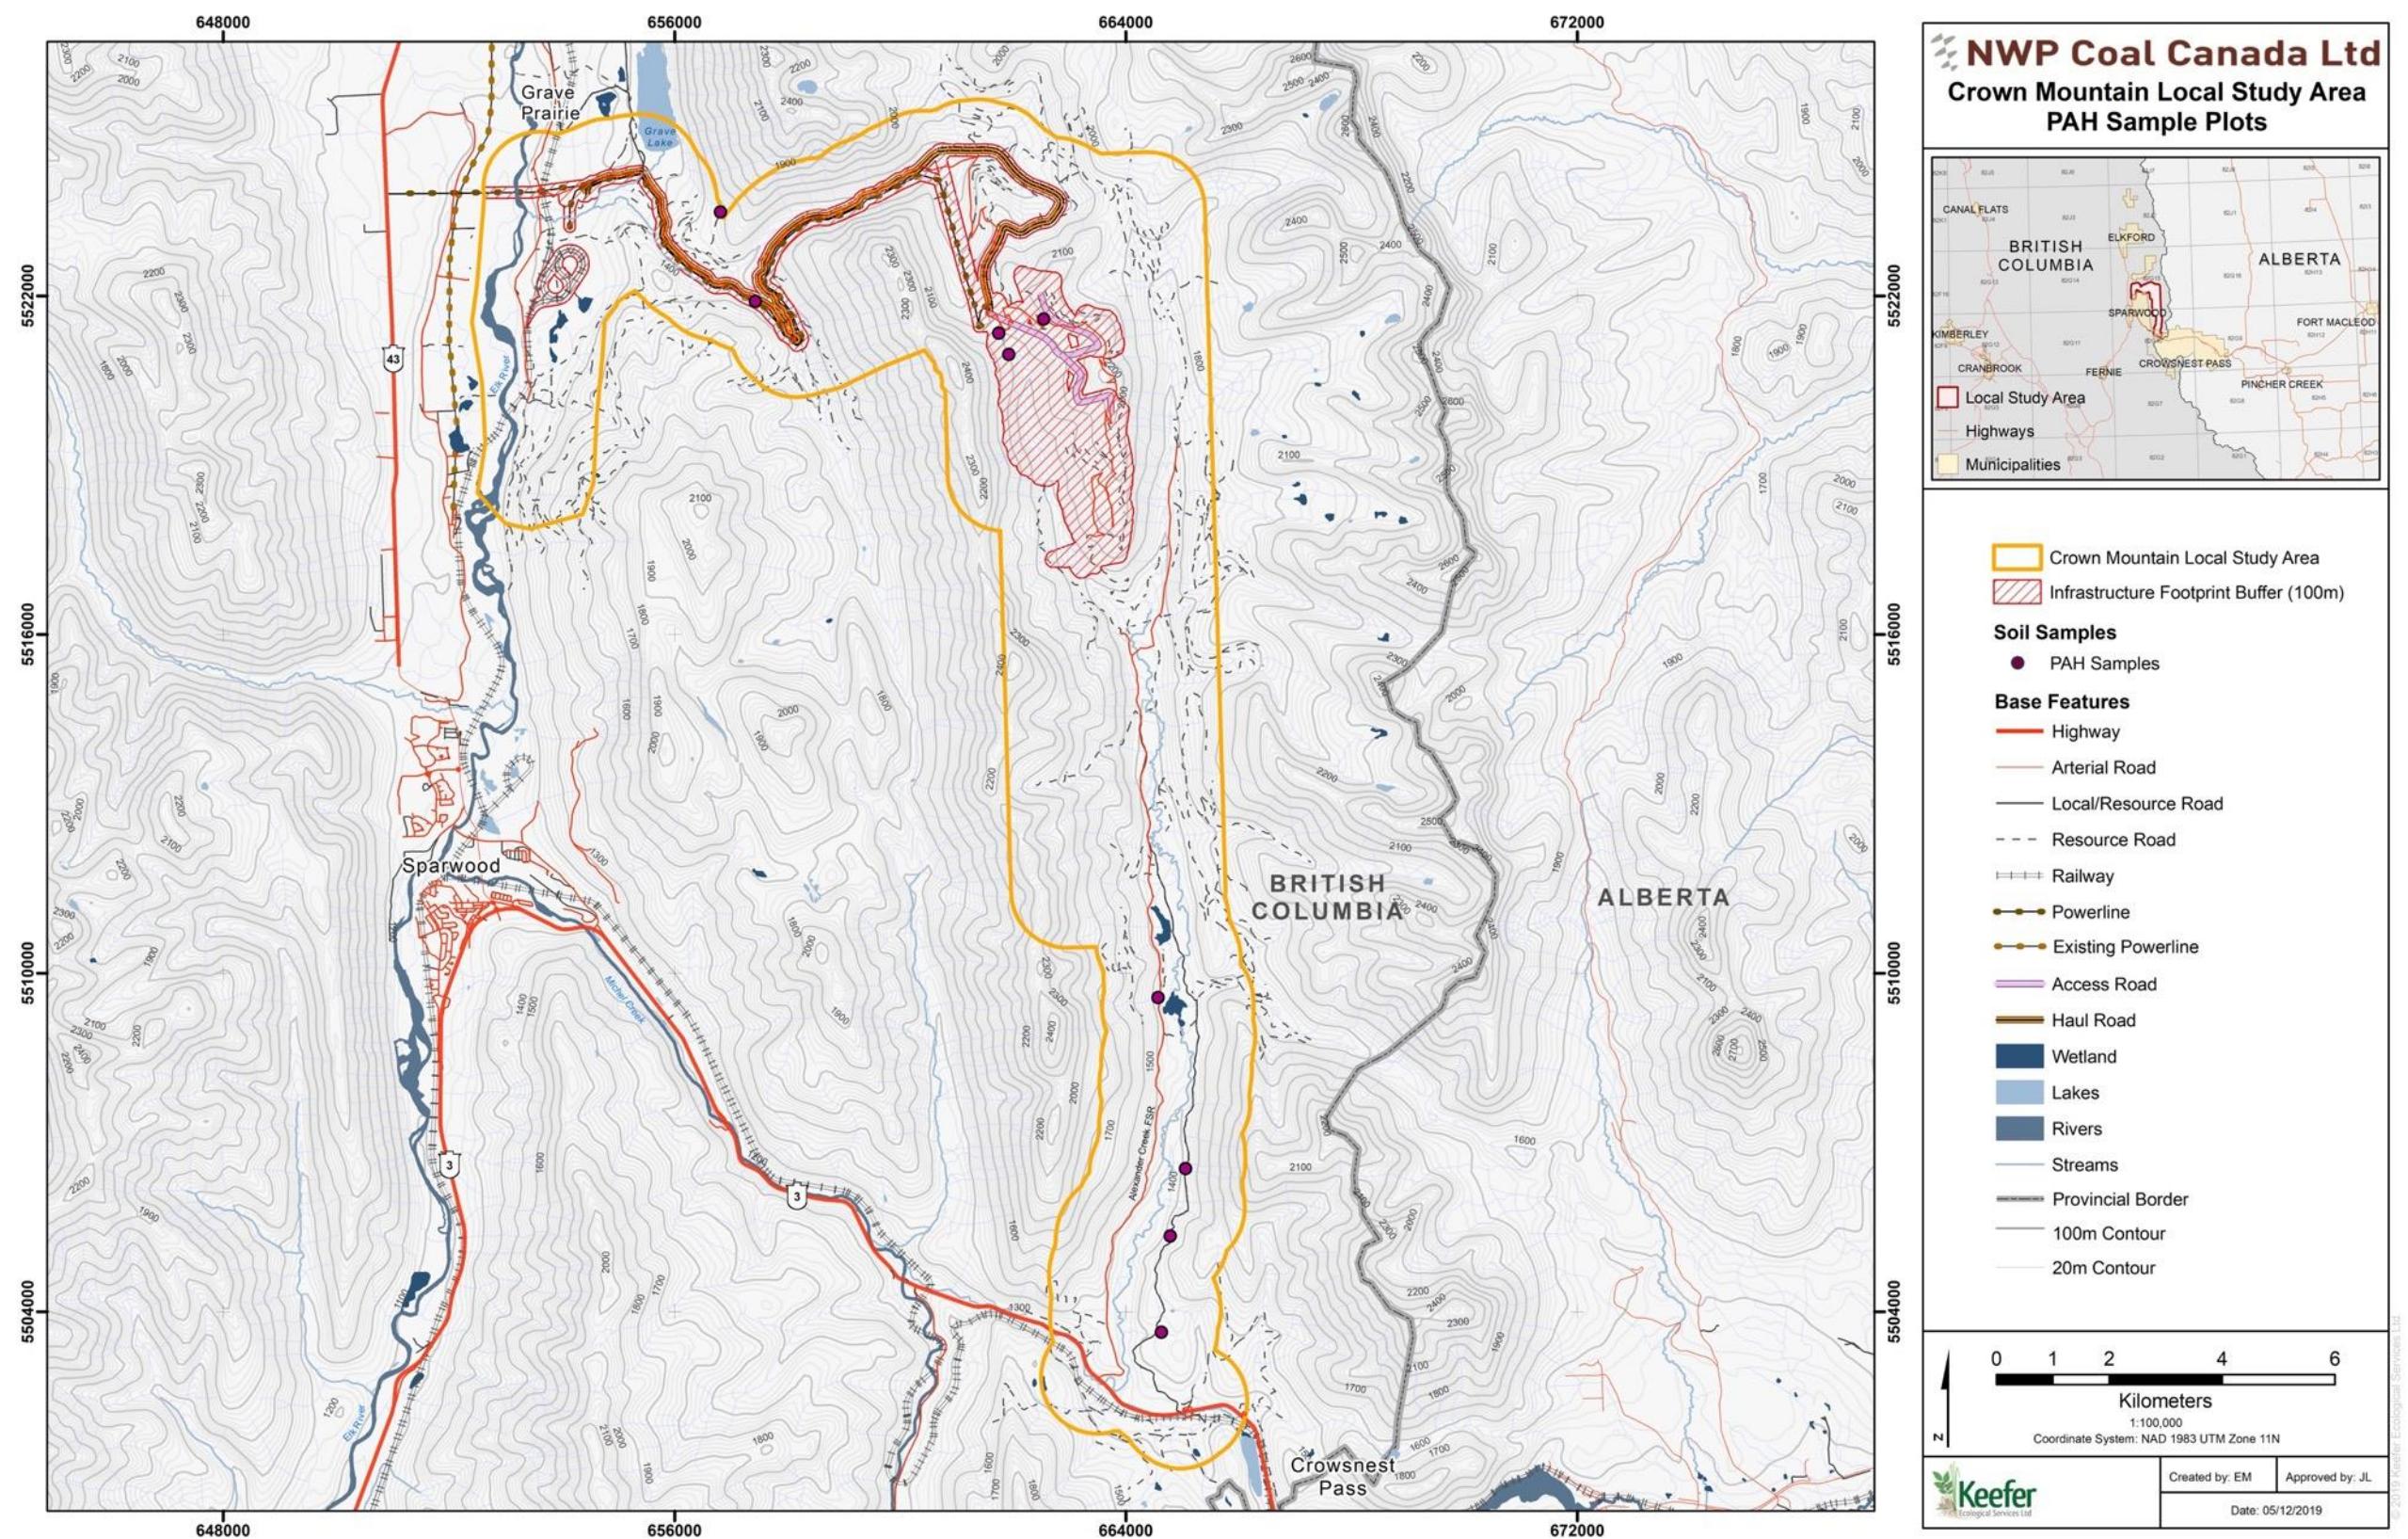

Figure 4-3. Sample locations for soil and vegetation samples submitted for PAH analysis.

4.2.2 Vegetation

The COAs (L1970983, L19778617 and L1974841), provided by ALS Environmental, showing PAH concentrations in vegetation samples collected is presented in Appendix 4. One plant tissue sample was submitted for PAH analysis for each species (Figure 4-3). In addition to the foliage/branch tip tissue samples submitted, berries were also submitted for PAH analysis for Saskatoon, rose, thimbleberry, elderberry and soopolallie. PAH analysis of the fruit of black huckleberry was not conducted as the poor berry crop prevented enough berries to be collected for analysis.

In total, 15 vegetation samples were submitted for PAH analysis (Table 4-12). 2-methylnaphthalene, Naphthalene, and Phenanthrene were the only parameters of the 17 analyzed that had resultant concentrations above the detection limit (Table 4-12). A black huckleberry tissue sample (sample 1) collected near an exposed coal seam northwest of the summit of Crown Mountain had the highest concentrations for 2-methylnaphthalene (0.156 mg/kg), Naphthalene (0.054 mg/kg), and Phenanthrene (0.095 mg/kg) parameters.

Statistical analysis was not completed for the PAH analytical results for vegetation samples as only a single sample was collected for each plant species and tissue type submitted. Alternatively, a direct comparison between the single samples of foliage/branch tips and berries of fruit-bearing shrub species was performed in place of statistical analysis (Table 4-13). The concentrations of all parameters, excluding 2-methylnaphthalene and Phenanthrene, did not differ between the foliage/branch tips and berries as all concentrations were below the corresponding detection limit. Concentration of 2-methylnaphthalene was greater in the foliage/branch tips than berries in the rose and black elderberry samples, as was Phenanthrene concentrations.

Detection limits were raised in cases where samples had insufficient volume, high moisture content, or high organic content, the detection limit was raised on a per-sample basis in the analytical laboratory⁷.

⁷ See *Detection limit policies: Reducing the chance of false positives due to sample-specific issues*. Retrieved from <http://www.alsglobal.com>

Table 4-12 Summary of PAH data analysis for vegetation samples (dry weight). Samples with highest (■) concentrations (mg/kg) are indicated. Raised detection limits (□) are also indicated. (□) is used to indicate where the highest concentration is above a raised detection limit.

4.3 Quality Assurance/Quality Control

In total, four field samples were submitted to ALS Environmental for QA/QC purposes for metal concentrations; beaked sedge foliage, rose foliage/branch tips and fruit, elderberry foliage/branch tips and fruit, soopolallie foliage/branch tips and fruit (Table 4-15). In addition, three field samples were submitted to ALS Environmental for QA/QC purposes for PAH; rose foliage/branch tips and fruit, elderberry foliage/branch tips and fruit, and soopolallie foliage/branch tips and fruit (Table 4-15). All QA/QC field samples are presented in Figure 4-4. ALS Environmental performs internal QA/QC, which is contained within each COA (Appendix 4).

Further analysis was conducted on these samples to satisfy the RPD requirement in the BC MWLAP sampling protocols (2013). The results of the RPD calculations are presented in Table 4-14.

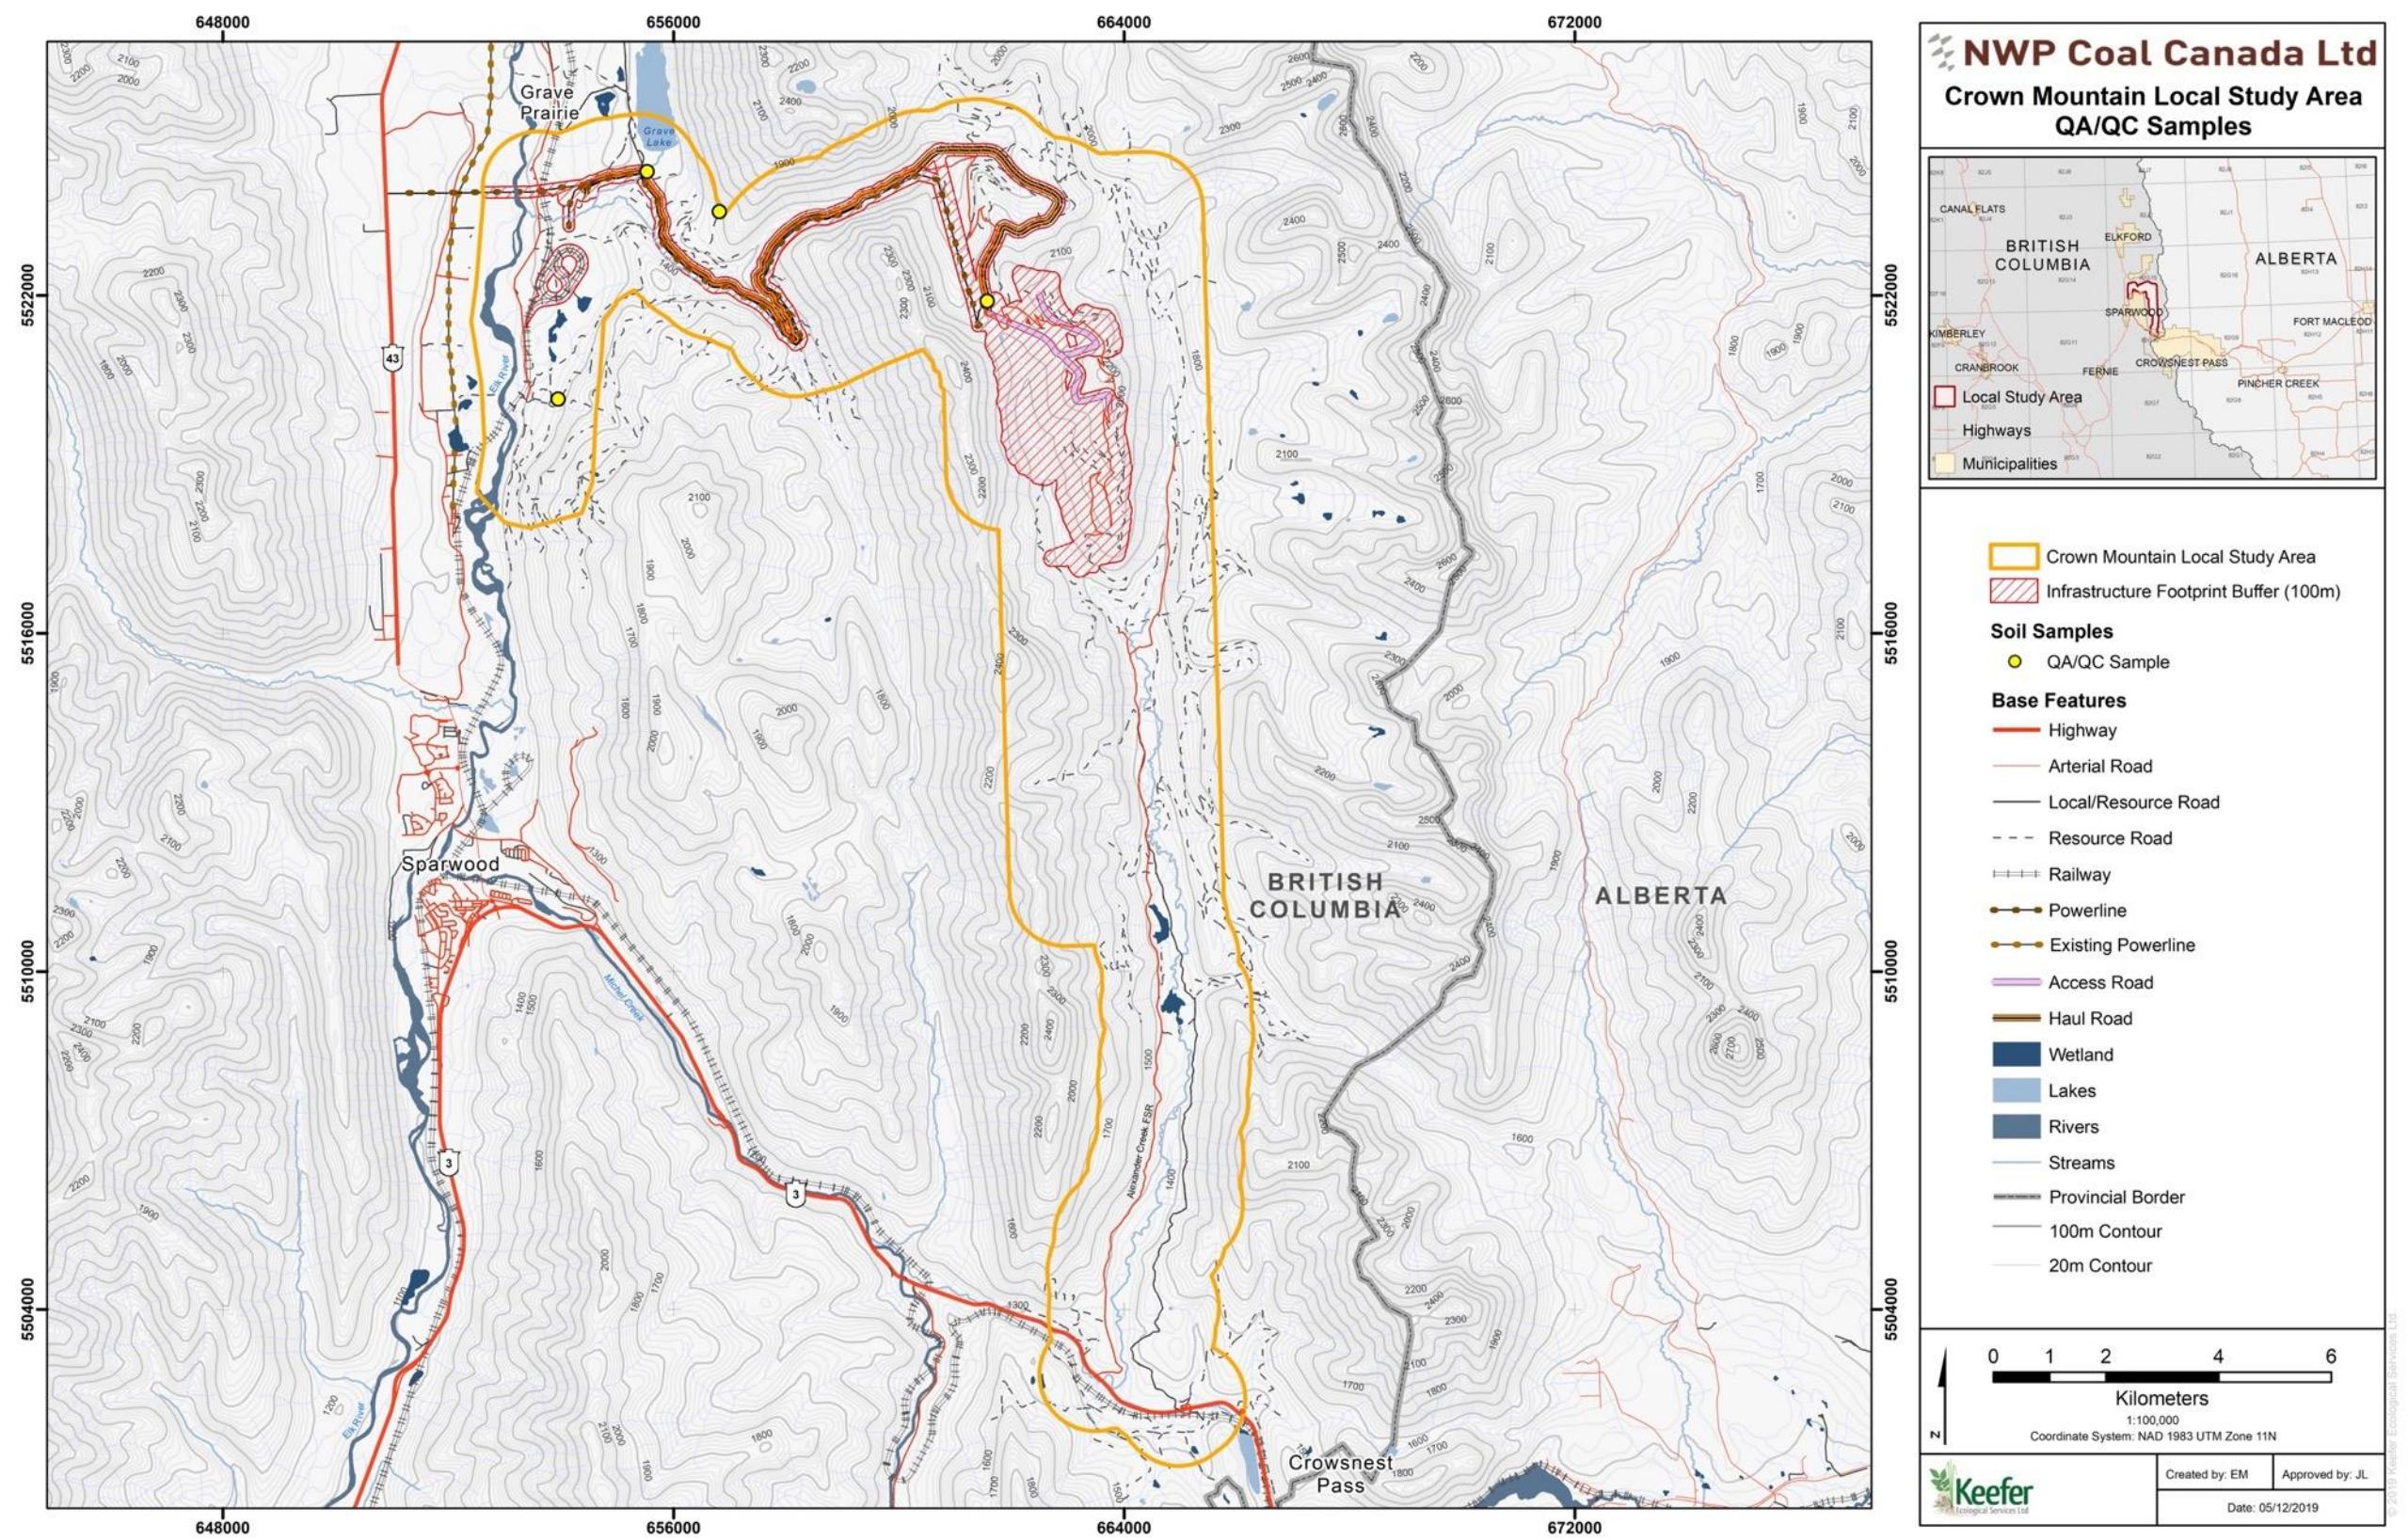

Figure 4-4. Sample locations for foliage/branch tip and fruit samples submitted for QA/QC purposes.

5 Discussion

The CCME guidelines for soil quality provide science-based goals for the quality of the terrestrial ecosystem. These guidelines are derived using toxicological data to determine the threshold level of effects for key ecological receptors (e.g., human health, soil invertebrates, wildlife species). In some instances, where CCME has not developed thresholds the BC Contaminated Sites Regulation may fill in the gaps. The CSR, under authority of the Environmental Management Act, sets out the requirements for site remediation in BC; thus, the CSR thresholds can be used as a maximum acceptable concentration value where CCME guidelines do not exist.

In the terrestrial environment, there are native vegetation species that are capable of extracting contaminants of concern and storing them in their tissues (e.g., sedges, cattails, willow species). Throughout the baseline chemical and soil classification and mapping surveys, soil and plant associations were observed that support this general understanding. Across the LSA, willow and sedge species were often associated with soil samples exhibiting high concentrations of metals (e.g., selenium).

5.1 Metals

Several metal exceedances were found throughout the LSA, across a variety of landscape features and soil types (Table 4-5, Table 4-7). Through the baseline chemical surveys, soil metal concentration exceedances were found for arsenic, barium, cobalt, nickel and selenium. Further, through the baseline soil classification and mapping surveys, soil metal concentration exceedances were found for aluminum, manganese, thallium and zinc.

According to CCME guidelines (1997), arsenic, which closely resembles phosphorous chemically, is a metalloid that exhibits both metallic and nonmetallic properties. It rarely occurs in its elemental form but often occurs as complexes with iron, nickel, copper and cobalt. This relationship may explain why samples with As exceedances also exhibited Ni exceedances (e.g., ROSA-06, 18-22-IIC). Arsenic is naturally present in the terrestrial environment from the weathering and eroding of rock and soil (e.g., glacial till). Arsenic is rarely found in higher concentrations in plant tissue than in their substrate (CCME, 1997), as demonstrated in the ROSA-06 soil, foliage/branch tips and fruit samples (Table 4-5, Table 4-8). Arsenic concentrations greater than 10 mg/kg have been found to reduce yield in vegetable crops (Woolson, 1973 as cited in CCME, 1997).

Nickel exceedances were observed along with As exceedances in the LSA. Nickel is naturally present in soils as a result of chemical and mechanical weathering of bedrock (e.g., granite, sandstone and limestone; CCME, 2015). Nickel is essential for plant growth; however, concentrations greater than 80 mg/kg dry weight have been found to have toxic effects (CCME, 2015). Nickel concentrations that exceeded the CCME guideline in the LSA were 50.6 mg/kg (ROSA-06, fine-textured glaciolacustrine soil) and 84.7 mg/kg (18-22-IIC, deep clayey parent material soil).

Barium is an alkaline-earth metal that readily oxidizes in air and reacts with water (CCME, 2013). Barium is ubiquitous in soils, though concentrations vary with bedrock geology (limestone, feldspar and shale deposits) and anthropogenic inputs. The mean background soil concentration of barium in Canada is 140 mg/kg (Grunsky, 2010 as cited in CCME, 2013). The soils sampled throughout the LSA ranged from 38 to 656 mg/kg (Table 4-5, Table 4-7). Higher levels of barium can be found as a result of leaching and eroding from sedimentary rocks and coal (CCME, 2013). Barium is also easily precipitated as sulphates and carbonates in soil. Several samples with barium exceedances were found on till or fluvial parent materials in the LSA (SHEPCAN-02, DY16, DY45), which often contain carbonates, as confirmed by a visible effervescence field test. Barium exceedances were also found in organic soil horizons in wetland soils throughout the LSA (CAREX-02, CAREX-03/EQUIARV-05, DY81), as barium can be found in groundwater as a result of leaching and eroding from rocks and soil (CCME, 2013). Barium is found in most plants, though little barium is bioaccumulated by terrestrial plants (Schroeder, 1970; WHO, 1990 as cited in CCME, 2013).

Selenium is a non-metal that occurs naturally in coal (CCME, 2009). Both anthropogenic and natural sources of Se contribute to its ubiquitous presence in the environment; a major anthropogenic source locally is through the extraction of coal, while the major natural sources include the weathering of rocks, minerals and soils (e.g., shale parent materials). Selenium is taken up by terrestrial plants in its soluble forms and is influenced by a variety of soil physical and chemical properties, including the total level of selenium in soil and the capacity of the plant species to accumulate Se (CCME, 2009). Selenium is translocated to all parts of the plant; thus, selenium concentrations in animal tissue tend to reflect dietary selenium concentrations (CCME, 2009). Selenium levels throughout the LSA were found to exceed the CCME guideline for residential/parkland (1.0 mg/kg), and often also the provincial guideline for wildlands natural (1.5 mg/kg). Of the soil samples that exceed the guidelines, Se concentrations range from 1.00 to 22.5 mg/kg (Table 4-5, Table 4-7). The vegetation samples collected in association with the baseline chemistry samples that were found to contain Se concentrations above the guideline were most commonly beaked sedge (*CAREX*) and willow (*SALIX*), both of which are known to accumulate heavy metals in their tissues (Drahonovsky et al., 2016; Pulford & Watson, 2002; Szucs, 2014).

Thallium and zinc exceedances were found in a till soil sample (DY46) from a rich, moist site in the western portion of the LSA. Thallium is a widely distributed, naturally occurring element in the earth's crust and is readily absorbed by the roots of most plants, likely due to its similarity to phosphorous (CCME, 1999). Zinc was also found in concentrations above the CCME residential/parkland guideline at 18-22-IIC (Table 4-6). Zinc is highly reactive in soils, though its mobility is predominantly controlled by pH (CCME, 2018b).

The province of BC, within its Contaminated Sites Regulation (CSR, 2019), has identified maximum allowable concentrations for metals and other substances in soil based on the land use specified for a site. These thresholds fill in gaps for substances not found within the CCME guidelines for soil quality. For example, the regulation provides thresholds for aluminum, cobalt and manganese, each of which were found in exceedance of the wildlands natural category of land use in the LSA. These thresholds are intended to inform reclamation practices.

5.2 PAH

The results of the PAH analyses for soil and vegetation samples collected throughout the LSA indicated, as expected, that PAH contamination is not prevalent. Most samples reported levels of PAH parameters at or below the detection limit. The most common parameters which recorded values above the detection limit, but below any environmental thresholds were 2-methylnaphthalene, naphthalene and phenanthrene. 2-methylnaphthalene is a naphthalene related-compound and, like naphthalene, is produced through incomplete combustion processes of wood and tobacco (ATSDR, 2005). Because 2-methylnaphthalene has similar chemical and physical properties, it is expected to act like naphthalene in air, water and soil. Naphthalene can dissolve in water and become weakly attached to soil; in air, it

degrades quickly. Phenanthrene is also created through the incomplete combustion of products like coal, oil, gas, and tobacco (US EPA, n.d.).

5.3 Quality Assurance/Quality Control

Quality Assurance/Quality Control was completed through the submission and analysis of duplicate vegetation samples. The results of the duplicate sample analysis are expressed as RPD; the lower the RPD value, the more precise the laboratory analysis. In accordance with BC MWLAP (2013), duplicate samples with a larger variation than 20% for soil, or 30% for vegetation indicate high sample variability which may be attributed to laboratory analysis, sampling technique (applicable for soil samples only) or natural sample heterogeneity. ALS Environmental noted high levels of sample heterogeneity overall.

For each QA/QC sample submitted to ALS Environment (soopolallie, rose, beaked sedge and elderberry), the RPD was calculated for each metal parameter ($n=33$) and, as ALS Environmental noted, high levels of sample heterogeneity was observed. The samples with the least amount of heterogeneity were rose foliage/branch tips and fruit (i.e., rosehips). The RPD for rose foliage/branch tip samples resulted in only six metal parameters exceeding the 30% threshold (As, Co, Cs, Cu, U and V); whereas, the RPD for rose fruits did not result in any exceedances (Table 4-14). In general, foliage/branch tips exhibited greater heterogeneity than fruit samples, as expected with sample composed of leafy and woody materials.

6 Conclusion

The baseline chemistry data collected and reported herein can be used to assess potential effects associated with the Project and provide a basis for mitigation, management, and monitoring requirements. Interpretation of metal and PAH chemical concentrations as tested by a qualified third-party analytical laboratory are to be conducted by a qualified third-party risk assessor for the purposes of informing the human and terrestrial wildlife health risk assessment for the Project.

Duplicate	Zirconium (Zr)-Total	DUP-H	L1970983-1, -10, -13, -17, -19, -3, -7, -8

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLCI	Detection Limit Raised: Chromatographic Interference due to co-elution.
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
DLQ	Detection Limit raised due to co-eluting interference. GCMS qualifier ion ratio did not meet acceptance criteria.
DUP-H	Duplicate results outside ALS DQO, due to sample heterogeneity.
SMI	Surrogate recovery could not be measured due to sample matrix interference.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
HG-200.2-CVAF-VA	Soil	Mercury in Soil by CVAFS	EPA 200.2/1631E (mod)
		Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAFS.	
HG-DRY-CVAFS-N-VA	Tissue	Mercury in Tissue by CVAFS (DRY)	EPA 200.3, EPA 245.7
		This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.	
MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)
		This method uses a heated strong acid digestion with HNO ₃ and HCl and is intended to liberate metals that may be environmentally available. Silicate minerals are not solubilized. Dependent on sample matrix, some metals may be only partially recovered, including Al, Ba, Be, Cr, Sr, Ti, Tl, V, W, and Zr. Volatile forms of sulfur (including sulfide) may not be captured, as they may be lost during sampling, storage, or digestion. Analysis is by Collision/Reaction Cell ICPMS.	
MET-DRY-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A
		This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).	
		Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.	
MOISTURE-TISS-VA	Tissue	% Moisture in Tissues	Puget Sound WQ Authority, Apr 1997
		This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.	
MOISTURE-VA	Soil	Moisture content	CWS for PHC in Soil - Tier 1
		This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.	
PAH-SURR-MS-VA	Tissue	PAH Surrogates for Tissues	SURROGATE
PAH-T-DRY-SOX-MS-VA	Tissue	PAHs in Tissue - dry weight basis	EPA METHODS 3540, 3630, 8270
		This analysis is carried out using procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846, Methods 3540, 3630 & 8270, published by the United States Environmental Protection Agency (EPA). The procedure uses a Soxhlet system to extract with dichloromethane, a subsample of homogenized tissue which has been dried with anhydrous sodium sulphate. The extract then may undergo a silica gel cleanup to remove polar organic compounds. The final extract is analyzed by capillary column gas chromatography with mass spectrometric detection (GC/MS). Because the two isomers cannot be readily chromatographically separated, benzo(j)fluoranthene is reported as part of the benzo(b)fluoranthene parameter.	
PAH-TMB-H/A-MS-VA	Soil	PAH - Rotary Extraction (Hexane/Acetone)	EPA 3570/8270

Reference Information

This analysis is carried out using procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846, Methods 3570 & 8270, published by the United States Environmental Protection Agency (EPA). The procedure uses a mechanical shaking technique to extract a subsample of the sediment/soil with a 1:1 mixture of hexane and acetone. The extract is then solvent exchanged to toluene. The final extract is analysed by capillary column gas chromatography with mass spectrometric detection (GC/MS). Surrogate recoveries may not be reported in cases where interferences from the sample matrix prevent accurate quantitation. Because the two isomers cannot be readily chromatographically separated, benzo(j)fluoranthene is reported as part of the benzo(b)fluoranthene parameter.

PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL
------------------	-------------	---	--

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60 C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

15-609383	15-609384
-----------	-----------

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

mg/kg - milligrams per kilogram based on dry weight of sample.

mg/kg wwt - milligrams per kilogram based on wet weight of sample.

mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.

mg/L - milligrams per litre.

< - Less than.

D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).

N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Duplicate	Manganese (Mn)	DUP-H	L1974841-14, -24

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DUP-H	Duplicate results outside ALS DQO, due to sample heterogeneity.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
HG-200.2-CVAF-VA	Soil	Mercury in Soil by CVAFS	EPA 200.2/1631E (mod)
		Soil samples are digested with nitric and hydrochloric acids, followed by analysis by CVAFS.	
MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)
		This method uses a heated strong acid digestion with HNO ₃ and HCl and is intended to liberate metals that may be environmentally available. Silicate minerals are not solubilized. Dependent on sample matrix, some metals may be only partially recovered, including Al, Ba, Be, Cr, Sr, Ti, Tl, V, W, and Zr. Volatile forms of sulfur (including sulfide) may not be captured, as they may be lost during sampling, storage, or digestion. Analysis is by Collision/Reaction Cell ICPMS.	
MET-DRY-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A
		This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).	
		Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.	
MOISTURE-TISS-VA	Tissue	% Moisture in Tissues	Puget Sound WQ Authority, Apr 1997
		This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.	
MOISTURE-VA	Soil	Moisture content	CWS for PHC in Soil - Tier 1
		This analysis is carried out gravimetrically by drying the sample at 105 C for a minimum of six hours.	
PAH-SURR-MS-VA	Tissue	PAH Surrogates for Tissues	SURROGATE
PAH-T-DRY-SOX-MS-VA	Tissue	PAHs in Tissue - dry weight basis	EPA METHODS 3540, 3630, 8270
		This analysis is carried out using procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846, Methods 3540, 3630 & 8270, published by the United States Environmental Protection Agency (EPA). The procedure uses a Soxhlet system to extract with dichloromethane, a subsample of homogenized tissue which has been dried with anhydrous sodium sulphate. The extract then may undergo a silica gel cleanup to remove polar organic compounds. The final extract is analyzed by capillary column gas chromatography with mass spectrometric detection (GC/MS). Because the two isomers cannot be readily chromatographically separated, benzo(j)fluoranthene is reported as part of the benzo(b)fluoranthene parameter.	
PAH-TMB-H/A-MS-VA	Soil	PAH - Rotary Extraction (Hexane/Acetone)	EPA 3570/8270
		This analysis is carried out using procedures adapted from "Test Methods for Evaluating Solid Waste" SW-846, Methods 3570 & 8270, published by the United States Environmental Protection Agency (EPA). The procedure uses a mechanical shaking technique to extract a subsample of the sediment/soil with a 1:1 mixture of hexane and acetone. The extract is then solvent exchanged to toluene. The final extract is analysed by capillary column gas chromatography with mass spectrometric detection (GC/MS). Surrogate recoveries may not be reported in cases where interferences from the sample matrix prevent accurate quantitation. Because the two isomers cannot be readily chromatographically separated, benzo(j)fluoranthene is reported as part of the benzo(b)fluoranthene parameter.	
PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL
		This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60 C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.	

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Reference Information

Chain of Custody Numbers:

15-609385 15-609386

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.

mg/kg - milligrams per kilogram based on dry weight of sample.

mg/kg wwt - milligrams per kilogram based on wet weight of sample.

mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.

mg/L - milligrams per litre.

< - Less than.

D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).

N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.

UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.

Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Appendix 5 Detection limits used by ALS Global for metal and PAH analysis of soil and vegetation samples

Detection limits for metal analysis of soil samples:

Metals (Soil)	Lowest Detection Limit (mg/kg)
Aluminum (Al)-Total	50
Antimony (Sb)-Total	0.10
Arsenic (As)-Total	0.10
Barium (Ba)-Total	0.50
Beryllium (Be)-Total	0.10
Bismuth (Bi)-Total	0.20
Boron (B)-Total	5.0
Cadmium (Cd)-Total	0.020
Calcium (Ca)-Total	50
Chromium (Cr)-Total	0.50
Cobalt (Co)-Total	0.10
Copper (Cu)-Total	0.5
Iron (Fe)-Total	50
Lead (Pb)-Total	0.50
Lithium (Li)-Total	2.0
Magnesium (Mg)-Total	20
Manganese (Mn)-Total	1.0
Mercury (Hg)-Total	0.0050
Molybdenum (Mo)-Total	0.10
Nickel (Ni)-Total	0.50
Phosphorus (P)-Total	50
Potassium (K)-Total	100
Selenium (Se)-Total	0.20
Silver (Ag)-Total	0.10
Sodium (Na)-Total	50
Strontium (Sr)-Total	0.50
Sulfur (S)-Total	10000
Thallium (Tl)-Total	0.050
Tin (Sn)-Total	2.0
Titanium (Ti)-Total	1.0
Tungsten (W)-Total	0.50
Uranium (U)-Total	0.050
Vanadium (V)-Total	0.20
Zinc (Zn)-Total	2.0
Zirconium (Zr)-Total	1.0

Detection limits for metal analysis of vegetation samples:

Metals (Vegetation)	Lowest Detection Limit (mg/kg)
Aluminum (Al)-Total	2.0
Antimony (Sb)-Total	0.010
Arsenic (As)-Total	0.020
Barium (Ba)-Total	0.050
Beryllium (Be)-Total	0.010
Bismuth (Bi)-Total	0.010
Boron (B)-Total	1.0
Cadmium (Cd)-Total	0.0050
Calcium (Ca)-Total	20
Cesium (Cs)-Total	0.005
Chromium (Cr)-Total	0.050
Cobalt (Co)-Total	0.020
Copper (Cu)-Total	0.10
Iron (Fe)-Total	3.0
Lead (Pb)-Total	0.020
Lithium (Li)-Total	0.50
Magnesium (Mg)-Total	2.0
Manganese (Mn)-Total	0.050
Molybdenum (Mo)-Total	0.020
Nickel (Ni)-Total	0.20
Phosphorus (P)-Total	10
Potassium (K)-Total	20
Rubidium (Rb)-Total	0.050
Selenium (Se)-Total	0.050
Sodium (Na)-Total	20
Strontium (Sr)-Total	0.050
Tellurium (Te)-Total	0.020
Thallium (Tl)-Total	0.0020
Tin (Sn)-Total	0.10
Uranium (U)-Total	0.0020
Vanadium (V)-Total	0.10
Zinc (Zn)-Total	0.50
Zirconium (Zr)-Total	0.20

Detection limits for PAH analysis of soil samples:

PAH (Soil)	Lowest Detection Limit (mg/kg)
Acenaphthene	0.0050
Acenaphthylene	0.0050
Anthracene	0.0040
Benz(a)anthracene	0.010
Benzo(a)pyrene	0.010
Benzo(b&j)fluoranthene	0.010
Benzo(b+j+k)fluoranthene	0.0150
Benzo(g,h,i)perylene	0.010
Benzo(k)fluoranthene	0.010
Chrysene	0.010
Dibenz(a,h)anthracene	0.0050
Fluoranthene	0.010
Fluorene	0.010
Indeno(1,2,3-c,d)pyrene	0.050
2-Methylnaphthalene	0.010
Naphthalene	0.010
Phenanthrene	0.010
Pyrene	0.010
B(a)P Total Potency Equivalent	0.020
IACR (CCME)	0.150

Detection limits for PAH analysis of vegetation samples:

PAH (Vegetation)	Lowest Detection Limit (mg/kg)
Acenaphthene	0.050
Acenaphthylene	0.050
Anthracene	0.050
Benz(a)anthracene	0.050
Benzo(a)pyrene	0.050
Benzo(b&j)fluoranthene	0.050
Benzo(g,h,i)perylene	0.050
Benzo(k)fluoranthene	0.050
