Executive Summary

Atlantic Mining NS Corp (AMNS), a wholly owned subsidiary of St. Barbara Ltd., is planning to develop the Fifteen Mile Stream Gold Project (the Project) located approximately 115 km east of Halifax, in Halifax County, in the province of Nova Scotia. Golder Associates Ltd. (Golder) has prepared hydrological models for the existing site conditions, as well as the operations and closure phases of the Project. The key objective of the hydrological modelling was to estimate the potential for change to surface water discharge in the receiving surface water environment that may occur as a result of the Project.

Hydrological models were developed using GoldSim Version 12.1. The modelling approach is a climate driven, water holding content-based watershed runoff simulation process, with integrated water inputs from process and site water contributions (e.g., effluent discharge, seepage). A stochastic modelling approach using a 56-year climate record provides a framework for the range of probabilistic climate conditions that the site and receiving surface water environment are likely to experience over the period of the Project.

The predicted potential changes for discharge, through the watersheds and receiving waterways, were compared between the existing conditions and those simulated during the operations and closure phases of the project. These potential changes were estimated and compared on a monthly timescale for dry, average, and wet climate conditions.

A discussion of the water quality predictions with respect to Project effects is presented in the EIS.

1.0 INTRODUCTION

To support the Atlantic Mining NS Corp (AMNS), a wholly owned subsidiary of St. Barbara Ltd., Fifteen Mile Stream project, Golder Associates Ltd. (Golder) has developed a hydrological model that is intended to provide predicted comparisons of change in the surface water flow system over the course of the Fifteen Mile Stream (FMS) project life cycle. This report details the inputs, methods, and results of the hydrological model and is complementary to the hydrological baseline report (Golder 2019a) and the Environmental Impact Study (EIS) for Fifteen Mile Stream.

1.1 Project Description and Footprint

The project consists of the following key components within the mine infrastructure footprint:

- Open pit
- Waste Rock Storage Areas (Potentially Acid Generating, PAG and Non-Acid Generating, NAG, Ore stockpile)
- Topsoil stockpile
- Till stockpile
- Tailings Management Facility (TMF)

These project components will be supported by required transportation and water management infrastructure, such as ditches, collection ponds, and treatment facilities, as required.

1.2 Baseline Hydrology

The Project site (referred to as the FMS Study Area in the EIS) is located in the northeastern portion of the Sheet Harbour watershed, which drains in a generally southerly direction from headwaters north of the Project to the Atlantic Ocean (Figure 1). The East River is the primary drainage feature in this watershed, and Fifteen Mile Stream is a tributary of the East River. Fifteen Mile Stream flows along the southwestern boundary of the Project site. Further details on the watersheds in and around the FMS Study Area are provided in Golder (2019a).

2.0 HYDROLOGICAL MODELLING METHODOLOGY

2.1 Model Framework

The hydrological model was constructed in GoldSim, an object-oriented simulation software (GoldSim Technology Group 2019). The AMNS GoldSim hydrological model (the model) for FMS was constructed to simulate the existing conditions, as well as the planned operational and closure phases, using primarily regional data scaled to the local watersheds. The model was developed to be run as a stochastic simulation, which allowed for the comparison and prediction of a range of potential hydrological conditions.

2.2 Model Phases

Separate hydrological models were developed for existing conditions and to align with the temporal boundaries used for the assessment of potential effects to surface water quantity, specifically:

Operations Phase

This phase will be initiated upon the start of ore extraction and processing and will cease once the economical ore reserves have been depleted and the mining processes have ceased.

Closure Phase

This phase will consist of the reclamation and post-closure stages:

- **Reclamation Stage:** Consists of the construction of the closure works at the site, as presented in the conceptual rehabilitation plan (McCallum Environmental 2019).
- **Post-closure Stage:** Consists of the period after the reclamation and closure works have been completed.

2.3 Watersheds

2.3.1 Watershed Delineations

Watersheds to be simulated were delineated for the key surface water flow paths through and around the FMS Study Area. The outflow of each watershed is aligned with those hydrometric monitoring stations installed in 2018 (Figure 2).

For the Operations and Closure phases, Knight Piésold (KP) developed water management plans and quantified the volumes of water that will be collected, treated (if required), and released to the environment (Appendix A). The facility footprints and associated water management features were provided by KP and the watershed areas removed or redistributed from the existing condition watershed (Figure 2). Watershed areas by phase are presented in Table 1.

Table 1: Watershed Areas

Watershed ID	Watershed Description	Existing Condition Area (m ²)	Operations and Closure Area (m ²)	Change in Watershed Area (%)
SW2	Seloam Lake Outflow	18,788,900	18,788,900	0
SW5	Seloam Brook at Fifteen Mile Stream	9,478,400	6,857,500	-28
SW14	Upper Reaches Fifteen Mile Stream	101,583,000	101,583,000	0

Watershed ID	Watershed Description	Existing Condition Area (m ²)	Operations and Closure Area (m ²)	Change in Watershed Area (%)
SW14A	Abraham Lake outflow at Fifteen Mile Stream	15,264,200	15,264,200	0
SW15	East Lake outflow	2,671,600	1,606,100	-40
SW15A	Eastern Tributary at Anti Dam Flowage	10,487,600	10,487,600	0
SW6	Anti Dam Flowage Outflow	18,694,200	18,592,900	<1
n/a	Mining Facilities Footprint	0	3,378,700	n/a
n/a	Total	176,967,900	176,967,900	0

2.3.2 Surficial Geology

Each delineated watershed was further characterized by the surficial soil properties (KP 2018a; Nova Scotia 2006). The resulting partitioning of the subject watersheds is summarized in Table 2 for existing conditions and in Table 3 for the Operations and Closure phases.

Table 2: Surficial Geology - Existing Conditions Watersheds

2.4 Climate

To confirm that the recommended site climate dataset was best represented by the long-term record at the Halifax Stanfield International Airport (KP 2018b), a review of regional stations and application of the inverse distance squared method (Dingman 1994) was completed. This method of climate location interpolation assigns a weight to surrounding regional climate stations based on the distance of the regional station from the Project site. Environment and Climate Change Canada (ECCC) regional climate stations selected in this analysis were the Halifax Stanfield International Airport (83 km from the project site; ECCC ID 8202250), Collegeville (53 km from the Project site; ECCC ID 8201000), Upper Stewiacke (39 km from the Project site; ECCC ID 8206200), and Stillwater Sherbrooke (43 km from the Project site; ECCC ID 8205601). Data for these stations were obtained from ECCC (2018). These stations had overlapping periods of record from 1980 to 2012, and the results of this review are summarized in Table 4.

Table 4: Total Annual Precipitation, Inverse Distance Squared Method

Description	Inverse Distance Squared Method predicted (mm)	Halifax Stanfield International Airport (mm)	Difference (mm)	Percent Difference (%)
Average Annual Total Precipitation (mm)	1272	1367	95	7

The predicted total annual precipitation for the Project site using the Inverse Distance Squared method was within 10% of the annual total recorded at the Halifax Stanfield International Airport climate monitoring station. As such, the Halifax Stanfield International Airport was considered an appropriate estimate of the climate at the Project site. This agrees with the conclusion of KP (2018b), where the Halifax station was noted as also having a long-term continuous record and is currently actively monitoring climate.

2.5 Hydrological Simulation Components

The hydrological model was constructed to simulate the potential for changes to streamflow in the studied watersheds. This streamflow was based on a soil moisture water budget approach (Holmes and Robertson 1959) following the form:

$$\Delta S = P + Q_{S_IN} + Q_{G_IN} + Anth_{IN} - ET - Q_{S_OUT} - Q_{G_OUT} - Anth_{OUT}$$

Where:

- ΔS is the change in storage within a soil or across a water cover.
- P is total precipitation; this is considered herein as the sum of rainfall and snowmelt.
- Q_{S_IN} is surface water input from upstream watersheds.
- Q_{G_IN} is groundwater input.
- $Anth_{IN}$ is anthropogenic input (e.g., treated effluent discharge).

- Q_{S_OUT} is surface water outflow.
- Q_{G_OUT} is groundwater loss.
- ET is evapotranspiration, which occurs at its potential rate (PET) when water is freely available at the soil or water surface. Soil moisture conditions can restrict evapotranspiration to an actual rate (AET).
- $Anth_{OUT}$ is anthropogenic output (e.g., freshwater removals).

Common units of the water balance approach are mm, which are then integrated over a watershed area (m^2) and time (e.g., days), to provide a total volume per duration (e.g., m^3/day).

2.5.1 Precipitation and Evaporation

As discussed previously, climate from the Halifax Stanfield International Airport (ECCC ID 8202250) was used as the basis for climate variability in the hydrological model. Monthly total precipitation, rainfall, snowmelt, and evaporation were provided by ECCC for the 54-year period of 1961 to 2015 (Appendix B). Monthly climate was sampled stochastically to provide the P and ET parameters for the water balance equation; stochastic modelling is further described in Section 2.5.7.

2.5.2 Groundwater

Net change to groundwater inflows to (Q_{G_IN}), and outflows from (Q_{G_OUT}) surface water systems, were provided by the concurrently developed FMS hydrogeological model (Golder 2019b).

2.5.3 Soil Storage

As shown in Table 5, a Water Holding Capacity (WHC) was assigned to each land cover/soil previously summarized in Table 2 and Table 3. The WHC acted as a reservoir (i.e., the ΔS in the water balance equation) to hold water available for evaporation or groundwater discharge. Runoff from each of the area-weighted WHCs occurred when no storage capacity remained in the land cover type. As such, a bedrock dominated component of the watershed (13 mm of WHC) was capable of filling with rainfall and snowmelt faster; therefore, capable of providing more runoff than a till-dominated watershed component (300 mm of WHC).

Table 5: Water Holding Capacity

Surficial Geology Type	Water Holding Capacity (WHC; mm)
Lodgement Till	350
Silty Drumlin	250
Stony Till Plain	350
Wetland	80

Surficial Geology Type	Water Holding Capacity (WHC; mm)
Alluvial Floodplain	300
Kettle Hole	200
Bedrock	13
Alluvial Outwash Plain	300
Organic Deposits	100
Kame Fields and Esker Systems	300

2.5.4 Reservoirs

Storage change (ΔS) in Seloam Lake and the Anti Dam Flowage were estimated through the development of a stage-storage relationship estimated from bathymetric mapping. P was added, and PET was withdrawn from the water surface and combined with the net discharge ($Q_{S_IN}-Q_{S_OUT}+Anth_{IN}-Anth_{OUT}$) through the reservoir, to result in the predicted change in storage for each of these elements.

2.5.5 Streamflow

Streamflow (Q_{S_IN}) was added from upstream watersheds to downstream watersheds, where applicable (e.g., from the Upper Fifteen Mile Stream watershed [SW15] to the Anti Dam Reservoir watershed [SW6]). Streamflow from a watershed outlet (Q_{S_OUT}) was the total discharge released by a watershed after ET was removed, soil storage was filled, and in the case of Seloam Lake and Anti Dam Flowage, reservoir operations were considered. Reservoir operations are further described in Golder (2019a).

2.5.6 Mine Site Water Management

Water storage and conveyance for the mine site components and related water management facilities were provided by KP for the Operations and Closure phases (Appendix A). For the hydrological model, the mine site water management schemes were incorporated through:

- Collection of water at and around the contributing catchments contributing to the mine site components and consequently reduction of natural drainage area to the existing hydrological system.
- Freshwater removal from Seloam Lake for process use ($Anth_{OUT}$ at approximately 360 m³/day during the Operations Phase).
- Treated effluent discharge to Anti Dam Flowage ($Anth_{IN}$, variable rate depending on phase; Appendix A).

At the Closure Phase and Post-Closure stage, the rehabilitation of the project footprint will be complete; KP completed a water balance for the site that is based on an annual runoff ratio value, where a proportion of

available water becomes site discharge each month. For environmental effects purposes, an alternative Post-Closure flow distribution was developed to align the closed watershed footprint runoff patterns more closely, with the natural watershed discharge estimates (i.e., the water balance equation above). This change altered the seasonal distribution of runoff from the closed and flooded Open Pit but did not affect the site runoff volume over the course of the year (Table 6).

Table 6: Effluent Discharge Alternatives

Month	Open Pit Discharge (m ³ , per KP, Appendix A)	Open Pit Discharge (m ³ , Alternative Strategy)
January	17,100	431,900
February	15,800	355,000
March	102,000	644,000
April	970,700	577,400
May	802,700	207,900
June	237,600	99,500
July	223,600	63,300
August	234,800	74,300
September	259,600	82,700
October	335,700	190,700
November	387,800	445,000
December	95,100	510,800
Annual	3,682,500	3,682,500

2.5.7 Stochastic Modelling

The hydrological model was run as a stochastic simulation where the 54 available years of climate data (P and ET) were input as monthly statistics. The stochastic sampling routine in GoldSim chronologically selected climate (P and ET) from each monthly distribution (i.e., a random January P and ET, a random February P and ET, etc.). Consequently, the model was capable of producing a variety of climate conditions within and outside of those recorded in the historical climate observations (Appendix B). Importantly, the model was limited to sampling climate parameters within each month; for example, a precipitation sampled for January was not concurrently sampled with an evaporation statistic assigned to July. One thousand iterations of the model were sampled, effectively representing a potential 1,000 alternative years of climate. For hydrology results, monthly model outputs were summarized statistically at the 5th and 95th percentile along with the mean of the 1,000 iterations.

3.0 MODEL RESULTS

3.1 Model Comparison to Regional Streamflow and Existing Conditions

The results of the existing conditions model were compared against the pro-rating of a regional WSC gauge (St. Mary's River) to the modelled watershed area. The general seasonal pattern and magnitude of the model matched with the pro-rated values, as well as the total flow predicted through the year; this indicates that the model was appropriately simulating the monthly changes in the hydrology of the Fifteen Mile Stream watersheds (Figure 3a and Figure 3b).

Results for the existing conditions hydrological model for the mean, 5th percentile, and 95th percentile surface water discharge through the modelled watersheds are presented in Appendix C.

3.2 Operations Phase

Results for the Operations phase hydrological model for the mean, 5th percentile, and 95th percentile surface water discharge through the modelled watersheds are presented in Appendix D.

3.3 Closure Phase – Reclamation Stage

Results for the Closure phase, Reclamation stage hydrological model for the mean, 5th percentile, and 95th percentile surface water discharge through the modelled watersheds are presented in Appendix E.

3.4 Closure Phase – Post-Closure Stage

Results for the Closure phase, Post-closure stage hydrological model for the mean, 5th percentile, and 95th percentile surface water discharge through the modelled watersheds are presented in Appendix F.

4.0 SUMMARY

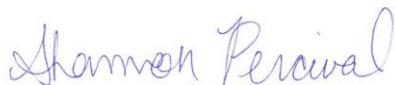

The hydrological models constructed in GoldSim for the FMS Project site integrated regional climate, surficial geology, and local reservoir properties, along with the planned water management for site infrastructure. Through stochastic simulation, a wide range of climate conditions were simulated, and the results of the hydrological simulations are further interpreted in the accompanying EIS.
